My bees have been gathering pollen every day since the 5th; they consume about one bucket of water daily (29 colonies); have brood in all the hives, and are all doing tiptop. Day before yesterday I neglected to put warm well water (74°) in my stone troughs, as is my custom, and the result was I had about half a pint of bees chilled, and in the cold water, in about three hours; but after taking them out, and putting them in a sunny place, they (with the exception of about half a dozen) came to themselves again and went to their respective homes. I give this merely as a caution to new hands at the business, not to supply their bees with ice water, at least in cold weather. M. BROERS.

Gonzales, Texas, Feb. 18, 1886.

Friend B., a bucket of water daily for 29 colonies is, I think, more than I ever knew bees to use before during the hottest weather. Didn't a great part of it evaporate?

HORSE-POWER FOR MAKING HIVES, ETC.

I see by GLEANINGS that you want to be posted in regard to the "Fearless" horse-power. I have had one in use for 20 years, and it is as good as new. I send you by to-day's mail an old circular. I think the machine a good one. GAIN R. SMITH.

Victor, Ont. Co., N. Y., Apr. 7, 1886.

Thanks, friend S., for your circular. Since your article was printed we have received quite a number of circulars in regard to horse-powers for hive-making. The tread-power is probably one of the best; but the one you mention as the "Fearless." we notice costs about $140. Circulars of other horse-powers have been sent us. We notice one from the Sandwich Mfg. Co., Sandwich, Ill., that costs only 30 or 40 dollars. Perhaps this latter will not give the power of the other, but it comes nearer within the means of the average bee-keeper.

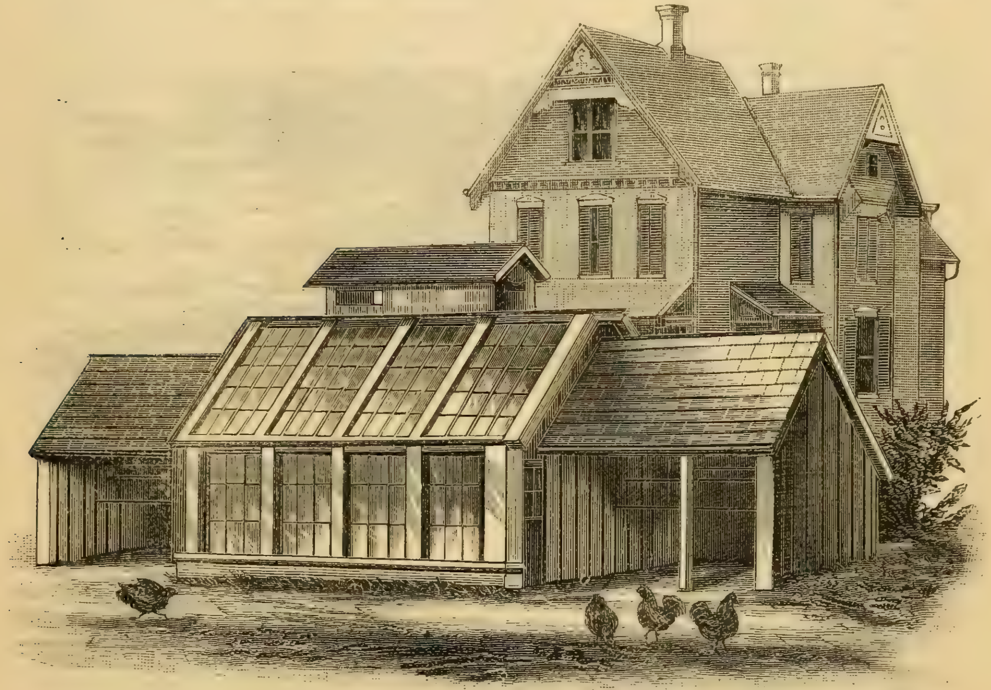
OUR POULTRY-HOUSE.

A BETTER PICTURE OF IT THAN WE GAVE LAST MONTH.

As the engravers disappointed us in getting our engraving ready, we were obliged to use, last month, a simple outline picture. Since then they have made so nice a picture that we concluded to give it here.

The large building in the background belongs to Neighbor H. You will remember that Neighbor H. and myself married sisters, so it comes about that we have houses on opposite sides of the street. Neighbor H. does not raise chickens—that is, he is not a chicken-man, although he gets a good many eggs in the good old-fashioned way by just letting the fowls "slide." He is a most enthusiastic bee-man, however, and just now his household, as well as the little cousins across the way, are full of enthusiasm over a new "queen-bee," in the shape of a new girl-baby, only about ten days old, belonging to him.

The picture of the poultry-house above shows very plainly the way in which the roosts run clear through the whole of the buildings, although the engraver forgot to put in the little doors that permit the fowls to sleep in the shed or in the inner apartment, according as the temperature of the weather may move them. During the winter we permitted the rabbits and Pekin ducks to occupy the yard with the fowls; but both have now been turned out for bad behavior. After I put them outside, every little while somebody kept telling me that my rabbits were loose, or that my ducks had got out. I replied by telling them that both had been excommunicated for bad conduct. The Light Brahmas are now the sole occupants of the yard, except a little Brown Leghorn hen that is my especial pet. She will let me pick her up any time I wish, even when she is walking across the lawn. She has raised one brood of chickens since the first of January, and is now diligently presiding over a sitting of thirteen. By the way, my heavy Light Brahmas don't work well as sitting hens, for they are so heavy they keep breaking the eggs. I fixed their nests in ever conceivable way, but they keep crushing their eggs with their great clumsy feet, no matter what I do, while my trim little bit of a Brown Leghorn covers about as many eggs as the Brahmas, and she was never known to break an egg in her life. It really seems as if she laid an egg every day of her life, when she is not sitting. It has been suggested, that the Brahma eggs have too thin shells. Now, they have bone meal right before them all the while; but somewhere I saw it mentioned in the poultry-journals, that overfed fowls are apt to lay very thin-shelled eggs, even if abundantly supplied with lime. May be that is the trouble; but I would much rather have it said that I feed my domestic animals too much than that I feed them too little.



OUR POULTRY-HOUSE AS IT APPEARS ON OUR GROUNDS AT THE "HOME OF THE HONEY-BEES."

Notes and Queries.

WANTED, IRON-CLAD, FROST-PROOF QUEENS FOR EARLY SHIPMENT.

COLD weather, not candy, caused the loss. We wish to breed an iron-clad, frost-proof bee for the early spring time. Our losses are being made good this week; weather superb.

J. W. K. SHAW & CO.

Loreauville, La., April 21, 1886.

[Quite a lot of queens, received when the weather was cold, from J. W. K. Shaw & Co., came through in bad order. When we suggested that the candy was too hard, they replied as above.]

WHITE-PLUME CELERY.

I find Henderson's White Plume a better keeper than has been claimed for it. I have it in fair condition now. E. W. SHATTUCK.

Springfield, Mass., Feb. 23, 1886.

[So do we.]

DWINDLING IN AUGUST.

Have you or any of your correspondents had their bees dwindle down in August, September, and October, from a large, heavy, and populous colony, to a very small one, say not more than half a pint to a pint of bees? and if so, what is the cause?

Dexter, Maine. L. FRENCH.

[We have never had bees dwindle down in August and September unless it was from the nameless bee-disease mentioned in GLEANINGS.]

THE PROSPECT FOR THE SEASON GOOD.

My 28 colonies of bees have come through the winter in fine condition on summer stands in Quinby closed-end-frame hives; they were packed with oats chaff, and covered with snow during all the cold weather. The prospect for the season is quite good. GREEN R. SHIRER.

Greene, Butler Co., Iowa, Apr. 14, 1886.

"NOT DISCOURAGED YET."

There was neither honey nor money about bees last season. I am not discouraged yet. I commenced last spring with 50 colonies; sold $60.00 worth of queens and bees, and took 300 lbs. of honey. I have reduced my stock by doubling. They are in good condition. The peach-trees failed to bloom this year, therefore the industrious little things have to be idle because there are no blooms for them to visit. W. D. THARP.

Williamsburgh, N. C., Apr. 9, 1886.

BARK-LICE NO MORE.

The bark-lice on the maple, I believe, are mostly dead. My reasons are, there was not much of a second flow of honey-dew last season. The bugs did not fasten themselves to the limbs as they did the year before. Many of them were found dead on the leaves, and the leaves hung on the trees unusually long, compared with the fall before. What are now on the trees, I am not sure whether they are mostly dead or alive. WILLIAM HALLEY.

Rockton, Ill., Mar. 20, 1886.

TWO BIRDS WITH ONE STONE.

I am constantly more and more convinced of the fact that raspberries should be more extensively planted by bee-keepers, because they are a profitable crop, besides the honey they furnish, the latter coming at a time when much needed, and being of an excellent quality. Hansell and Cuthbert, for early and late red varieties, are among the best, I think, while I should prefer Tyler, Souhegan, Ohio, and Gregg, for blackcaps, and Shaffer's Colossal, a cross between the black and red varieties, to cap the list; it is the most productive variety I have ever seen. Its growth is simply wonderful, and the berries delicious. Why search for the half-stunted berries, by miles of tramping, when the waste ground about home would be improved, and your health and comfort as well, with an abundance of berries?

C. WECKESSER.

Marshallville, Wayne Co., O , Apr. 12, 1886.

THE SHIPMAN ENGINE JUST THE THING FOR BEE-KEEPERS.

I see that you have a Shipman engine. My partner and myself have one also (a one-horse power), which we use in making Simplicity bee-hives. We run one of Barnes' foot-power saws, and another 7-in. circular saw on one of your $7.00 mandrels at the same time, cutting ⅞ pine—just the thing for bee-keepers wanting small power.

W. J. KINCHELVE.

Narrow Rock, Mo., Jan. 6, 1886.

THE NEW BARNES FOOT-POWER SAW.

In replying to your request in GLEANINGS, I will say that I don't know that I am capable of passing judgment on the new Barnes saw, as I never had experience with that kind of machinery; but I will say that it gives good satisfaction, and does fine work if your lumber is free from any warp; but if it is the least warped, in cutting off end bevels you will have trouble. WILL T. ZINK.

Nichol, Greene Co., Mo., Mar. 7, 1886.

ITALIANS GREATLY SUPERIOR TO BLACK BEES.

I consider that it pays to Italianize. Mine were all blacks and hybrids last spring except 3. I extracted from one Italian swarm about 140 lbs. of nice clover honey; while from a black swarm sitting by its side, I got only about 15 lbs. Am expecting better results this year than last. I should have got three times as much honey last year as I did, but I was Italianizing my apiary, and had several hives queenless at the wrong time, which I will not do again. We must live and learn.

THOMPSON BROWN.

Cloverdale, Ind., Jan. 1, 1886.

THE RESULTS OF REVERSING DARK HONEY.

There is one thing about reversible frames and brood-chambers that I should be pleased to have explained. How is it possible to prevent the dark honey, which accumulates in the upper corners of brood-frames, from being carried into the sections when the frames are reversed? In some localities quite a little dark honey is gathered before clover-bloom. If, when clover begins to bloom, the reversal of the brood-frames results in scattering this dark honey through the sections, it would seem not to be desirable. M. FRANK TABER.

Salem, O., Mar. 22, 1886.

[Friend T., we have had so little experience in reversing frames that we can not answer your question; but I do not imagine that the difficulty you mention would occur often enough to be any great detriment.]

SEEDING DOWN WASTE ROAD-SIDES.

Honey-producing plants are scarce here, and bees can just about make a living. I am in hopes to do better when I get some alsike growing. I have been plowing the road-side, and now have it in good shape, with deep dead furrows on each side. I will now seed down, expecting to get some honey and hay, besides keeping bad weeds from seeding. I think all roads ought to be fixed that way. The good looks will nearly pay, and leave the crop for profit. ELIAS EVERITT.

Philo, Ill., Feb. 23, 1886.

CAN THE SCREW-CAP CANS BE USED FOR OTHER PURPOSES THAN FOR HONEY AND SYRUP?

We received the 20 lbs. of California honey today. It was packed very nicely, and the honey is excellent. Could we use those screw-cap cans instead of fruit-jars, for berries, tomatoes, etc.?

Elkhart, Ind., Apr. 22, 1886. M. MATUSZKIEWITZ.

[Friend M., we do not know of any reason why these cans wouldn't answer for any thing where self-sealing fruit-jars are used. May be it would be necessary to use small rubber bands around the edge of the screw caps, to make it fit absolutely air-tight.]

DRONES OUT OF SEASON.

You will see by this that my hopes are not "busted" so far this winter as they were last. I put 46 colonies in the cellar the 6th day of Dec., and Feb. 23d I took 46 live colonies out for a fly, all in good condition but one, and in that one I found drones crawling and hatching, and what I supposed to be drone-eggs. I pinched the queen's head off. Did I do right, or should I have left her to rear early drones?

WHAT DOES IT?

In carrying out my bees I found nearly all the dead bees had holes bitten in the back of their heads, and a great many bitten clear into their heads. If you can answer this you will oblige.

Orion, Wis., Feb. 26, 1886. F. L. SNYDER.

[You are probably right, friend S., in destroying any queen that produces drones in February. Young queens, when they first begin to lay, will oftentimes produce drone-brood for a little while, and then worker-brood afterward. The holes in the back part of the heads and bodies of your dead bees were probably made by mice—possibly by ants, if they were where ants had access.]

DO BEES POISON HONEY WITH THE VENOM OF THEIR STINGS?

A correspondent of the *Country Gentleman* advances the theory that honey is sometimes poisoned by the venom from the stings of infuriated bees, so as to be quite injurious to eat in large quantities. This is especially apt to be the case when the bees are roughly handled or greatly irritated, when the honey is removed. Gentle treatment he regards as the best remedy for such trouble. What is your opinion on the subject?

ESTELLINE H. WILLIAMS.

Maysville, Ky., Feb. 2, 1886.

[This theory was advanced years ago; and Mr. Langstroth, in his writings, alludes to it; but I do not know that we have had any very positive facts to substantiate it. It has been suggested that honey, heated almost to the boiling-point, is rendered more wholesome.]

HOW SHALL WE PUT UP OUR EXTRACTED HONEY?

Here is my answer: Go to the stores and places where they use large quantities of kerosene oil, and buy the empty cans at 10 cts. or less, and engage the boxes they were shipped in, at 10 cts., of your grocery merchant. Unsolder the patent nozzles, and take them out. Three boxes of lye will clean 30 or 40 cans, and you can do the work in half a day. Repair the holes that have been cut or punched in the cans, or get your tinner to do it. You can put in honey-gates, or you can take a piece of tin, and solder the cans up when they are filled. Put them in the boxes, and they are ready to ship. Two cans holding 120 lbs., and the shipping-box, ought not to cost over 40 cts. I hauled 1400 lbs. of honey, put up in this way, with straw packed under it, in a wagon nearly 250 miles, and all the cans were sound and good at the end of the journey. If you want me to do so, I will tell you how to clean the cans. J. M. KILLOUGH.

San Marcos, Texas, April 21, 1886.

SAND-BEES.

Prof. A. J. Cook:—I send you by mail herewith, a specimen, which please notice in GLEANINGS, if there is any thing of interest connected therewith.

Hudson, Mich., Apr., 1886. A. D. ARMSTRONG.

This is one of our common sand-bees, of the genus *Osmia*—see Manual, page 29. They live solitary lives, and not in colonies. They often steal into the hives of the honey-bees, to rob the latter of their stores. This one is beautiful in color, and a little smaller than the worker-bee. A. J. COOK.

Agricultural College, Mich.

SWEET CLOVER; WHEN AND HOW TO PREPARE THE GROUND FOR.

I wish to sow a piece of heavy clay land with sweet clover. It was in corn last year. Will you please tell me how to manage it to the best advantage? Shall the seed be sown by itself this spring, or is there danger of the weeds choking it if sown in this way? How would it do to sow it with oats, or with buckwheat? Will it freeze out on clay land?

Salem, O., Mar. 22, 1886. M. FRANK TABER.

[Friend T., I think your cheapest way will be to sow clover seed with the oats. There is no danger of any thing choking it. In fact, it will grow on the most barren hill-side, or even in a hard road-bed, and oftentimes it makes a most luxuriant growth where nothing else would think of growing.]

KEEPING SURPLUS QUEENS FOR SHIPMENT.

I should like to know how you keep queens a month in the office. FERGUSON WHITESIDE.

Little Britain, Ont.

[Friend W., we do not ordinarily keep queens a month, yet we can do it by giving them fresh bees every few days, and keeping the sugar in the queen-cages saturated with freshly gathered honey. We seldom keep them longer than a week; for if we get so many ahead as to cause such a state of affairs, we prefer to divide colonies and use them to start nuclei.]

TOBACCO COLUMN.

A SHORT SERMON ON TOBACCO; FROM A FRIEND WHO LETS GO OF THE PLOW-HANDLES LONG ENOUGH TO REPLY TO THE GALLIPOLIS JOURNAL.

S. DANIELS, Pine Grove, Ohio, sends us the following clipping from the Gallipolis *Journal*. It contains so many sharp hits that we here present it to our readers who may have an interest in the Tobacco Column:

MR. NASH:—In your last issue I noticed that you wanted to hear from the farmers on the tobacco question.

Now, my hand fits the plow-handle much better than a pen, and my intellect has been trained to raise fat pigs and big pumpkins; consequently my patch of literature has been sadly neglected, but I will try.

I notice that your Board of Trade is to be solicited to issue a pamphlet on tobacco. Now, I should like to make a few suggestions as to what it should contain.

I should like for it to contain the name of the man who can stand up and truthfully say that the first tobacco that he placed between his molars tasted good.

Also the mother that advises her sons to chew tobacco, and the father who is proud of his daughter because she can smoke a pipe and dip snuff.

I want to hear of the physician in good standing that recommends his children to use tobacco.

I should like it to contain, also, the name of the young man that would prefer a bride with a pipe in her mouth.

Also the name of the man that has good sound sense, and has used tobacco ten years, that has not wished himself clear of the habit scores of times.

I should like to have the address of the man who can live on tobacco alone and nothing else.

I should like to have the name of the young man that offers his best girl his plug of natural leaf and a stoga.

Young man, she has just as good a right to use it as you have.

Please have the name of the man inserted whose breath is improved by the use of tobacco.

I want it to inform me where I can procure a suit of clothes that could be improved by blotches of filth from a tobacco-chewer's mouth.

Also have it contain (in large type) the advantages the tobacco-consumer has over one who does not indulge.

If tobacco is good to chew, why is it not good to swallow? Please publish the reason.

It is my opinion, Mr. Editor, that tobacco is a curse to the American people, socially, physically, and financially; and that the raising, manufacturing, selling, and consuming, should be everlastingly sat down upon by all good citizens; and if your Board of Trade has nothing better to do than to enhance the popularity of tobacco, they had better trade themselves off for a yaller dog and then get some friend to shoot the dog; for the man that raises one good potato does mankind more good than he who raises tons of tobacco. BUCK I.

We think of coming up and seeing your apiary some time. I have quit using tobacco, after using it for two years. I used to be a lover of it. If you think me entitled to a smoker, send me one.

ISAAC THROSIKILL.

Barber's Mills, Wells Co., Ind., Mar. 8, 1886.

We should be happy to see you, friend T. Sometimes we are "awful" busy, but we generally contrive to make it pleasant for visitors.

I have used tobacco 35 years. If you will send a smoker I will quit the habit or pay for the smoker.

W. P. MCNAMEE.

Houston, Chickasaw Co., Miss., Feb. 22, 1886.

Please send me your smoker, as I have none. I quit chewing tobacco some time ago, and I heard you would send a smoker to all who have quit its use.

Hartwell, Ga., Mar. 13, 1886. W. M. VICKERY.

As I use tobacco, and am to a limited extent in the bee-business, I send in my petition, with the promise that, if I ever use the vile weed again, I will pay you double price for the smoker. W. W. GRANT.

Marion, Williamson Co., Ill., Feb. 19, 1886.

I promise to pay for the smoker if my father ever returns to the use of tobacco. ALBERT CUSICK.

Hartwick, Osceola Co., Mich., March 8, 1886.

Accept my thanks for the smoker. I am well pleased with it; and if I ever use tobacco again I will pay you for the smoker. JOHN BECKWITH.

McLean, Tompkins Co., N. Y., Mar. 6, 1886.

QUITS AT 45 YEARS OF AGE.

Pa asks me to write to you. He is a man of about 45 years of age, and has been using tobacco for a good many years. He declares he will never use it again, and asks you to send him a smoker. If he ever uses it again he promises to pay for the same.

T. F. SHEPHARD.

Franklin, Venango Co., Pa., Mar. 20, 1886.

After using tobacco about 15 years, I will quit, and expect never to use it again. If you think I deserve a smoker, please send me one; and if I take up the habit again I will pay for the smoker.

JACOB GEISER.

Goshen, Ringold Co., Ia., March 11, 1886.

ANY ONE CAN QUIT.

I smoked for 20 years, so much that it was a common saying in this neighborhood that, if my pipe were to be found cold, it would be known that I was dead; but I have not tasted tobacco for over two years. If I could quit, any one can, if he wants to. J. H. TINKER.

Olathe, Kan., Mar. 6, 1886.

TWO FRIENDS HAVE GIVEN UP THE HABIT.

In compliance with the request of my friends, A. S. Hulbert and C. H. Mills, I write you to send each of them a smoker by mail to Rozetta, Henderson Co., Ill. They have stopped using tobacco, and promise to pay for the smokers if they commence again. H. G. GILBERT.

Monmouth, Warren Co., Ill., Feb. 11, 1886.

I saw in GLEANINGS that you would give a smoker to any one who would quit the use of tobacco. I haven't used it in any way since last October; but I was a great slave to it up to that time—20 years at least. I did not quit using it to get a smoker; but I promise that if you send me one, if I ever use tobacco again I will pay you for the smoker.

C. M. SMITH.

Turnersville, Coryell Co., Tex., Feb. 16, 1886.

A "DOSE OF TRUTH" FOR ONE WHO POINTS OUT THE WAY OF TRUTH.

I have taken the "Dose of Truth." I agree that it shows why the tobacco habit is a growing sin, and, like snuff among females, is one of the worst of habits. Our clergyman, Rev. E. H. Dixson, Staunton, Fayette Co., O., is an inveterate chewer. If you will not accept pay for the Dose of Truth, please send our minister one. L. F. HOUSE, M. D.

Selden, Ohio, March 16, 1886.

QUIT USING TOBACCO AFTER TAKING GLEANINGS.

I have quit using tobacco since I commenced taking GLEANINGS, after using it 40 years, and I have not used it since Jan. 1st. If you think I am entitled to a smoker, send me one, and if I commence to use tobacco again I will pay you for it.

We have 30 colonies in Simplicity hives, and one in Root's chaff hive. I am very fond of GLEANINGS. JOHN BECKWITH.

McLean, Tompkins Co., N. Y., Feb. 23, 1886.

BECAME A TOBACCO-USER IN ORDER TO MANAGE BEES IN THE GOOD OLD WAY.

When I got my first swarm of bees, folks all told me I would have to use tobacco smoke in the good old way, to subdue them. That way was with the pipe. I couldn't tell at first which was the worse—the smart of a bee-sting or the sickness from the pipe; but I hung on to the pipe; then, to be more fashionable, I occasionally changed to a cigar; but now I have resolved to quit. No more of my bees will get the full blast of a pipe or cigar, if you will send me one of your smokers. I think the chaff hives are the hive for this country.

Ilesler, Owen Co., Ky., Mar. 15, '86. J. T. RUSH.

COMFORT FOR THOSE WHO HAVE LONG BEEN USERS OF THE WEED AND DESIRE TO QUIT.

I often think if I could wield the pen as well as I can handle the plow I would write for the tobacco column—not for the purpose, however, of obtaining a smoker, for I have one, but for the purpose of relating my own experience with the weed, with the hope that it would do some poor slave to appetite good to see how one who has been a slave for thirty years had got rid of the habit, and for several years has been breathing the pure air of freedom, except only when coming in too close contact with some one who was polluting it with the fumes of his pipe or cigar. J. A. HAUGHEY.

Sabina, O.

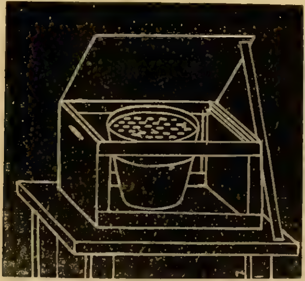
OUR OWN APIARY.

NUMBER LOST DURING THE PAST WINTER.

WELL, friends, two more colonies have been added to the death-list since our last report. The cold spell of weather during the first week in April, together with the heavy fall of snow, was too much for these two colonies. One of them, besides being weak, was queenless; the other was also weak, and during the cold had deserted their brood for one corner of the hive, where they perished. The total number of colonies lost the past winter is now five, or a loss of something less than 3% of the number put into winter quarters last year. Oh that we hadn't lost *any!* Suppose our bees had been fed on sugar stores, then what? No one can tell.

We have not had a single case of "spring dwindling," and the hives inside look comparatively clean; *i. e.*, not spotted in a manner to indicate the presence of dysentery. At this date, April 23, the colonies seem vigorous and healthy, averaging from 3 to 5 lbs. of bees per swarm. It will be remembered that all our bees had nothing but their own natural stores, and in many cases it was found there was considerable pollen in the frames of sealed honey where we had supposed that there was an absence of it. At any rate, it did no particular harm, and in many instances it was just what was wanted to start brood-rearing.

Natural pollen is now coming in at a pretty fair rate from the dandelion and fruit-bloom, which is just beginning to appear.



ANOTHER WAX-EXTRACTOR.

Hugh Vankirk, of Washington, Pa., has ingeniously extemporized a solar wax-extractor, made from an ordinary 48-lb. shipping-case, such as we advertise. Those who have had such a shipping-case will remember that the ends are rabbeted out on the inside, in such a way as to let the cover drop down plumb even with the top. Into these rabbets our friend drops a sheet of glass, cut from an old window-pane to the size of the cover. A flat gallon crock, into which is fitted a common cullender, is placed inside. This answers the purpose of the dripping-pan as well as the perforated metal. The wooden cover to the shipping case is painted black, to draw the sun's rays. This is then, by means of a stick, held at the angle that will secure the best results. The whole is now complete, and its manner of using is illustrated in the cut. The scraps of wax can now be placed in the cullender over the crock, and in a short time, no doubt, a nice yellow cake of wax will be found in the bottom of the crock. The cakes, if the odd scraps of wax were not too dirty in the first place, will not have to be melted over again in pans, but are just the right size for commerce. The sides of the case being open, the sun will strike the sides of the crock. This, being of a dark color, will draw a good deal of heat. In regard to its working, our friend speaks of it as follows:

> I took the extractor out and set the case right down in the snow. I then put in the wax and left it for some time; but when I went back the wax was all melted and run through the sieve in the crock. I thought that was melting two pounds of wax in a short time, and this for a little money. I think it would be hard to beat, for the lid can be painted black, and used for a reflector, and it adds to the case only the price of a glass 18⅛×12 inches wide, and a sieve and a crock, which almost any one has. I must say I did not think it would melt wax when snow was on the ground.
>
> Washington, Pa., April 8, 1886. HUGH VANKIRK.

I would suggest, that, instead of having the cover painted black, we use a sheet of tin for a reflector, and that, where we do not have any old broken panes of glass large enough, we can slip out one of the sheets of glass in the sides of the case. This is of just the right length, but it is a little narrow. Either a narrow piece of glass can now be fitted in, or the other sheet can be drawn out of the other side, and the two sheets be made to lap easily. The sides vacated by the glass will have to be covered over with strips of boards to hold the heat accumulated. I have no doubt the extractor will work well, and friend V. deserves our thanks.

E. R. ROOT.

SOMETHING FROM PROF. COOK IN REGARD TO PRIVIES, ETC.

THE DRY-DUST ARRANGEMENT AS IT IS USED AT THE GROUNDS OF THE AGRICULTURAL COLLEGE.

THE recent articles in GLEANINGS in reference to privies are certainly called for, and hence are opportune. I think you once described ours briefly. It has been so entirely satisfactory for ten years that I am led to give a description again, and more in detail.

Three things are required in a perfect privy. Convenience, neatness, and safety. Convenience suggests that it be in the house, under the same roof; neatness, that it be always clean and inodorous; safety, that it can not possibly pollute the soil, and through that the well and drinking-water. Ours has fulfilled all these requirements for several years. It is situated in the back corner of the woodshed, three feet from the ground, and on the same level as the kitchen-floor. Old people and children can visit it as easily as they can pass from one room of the house to another.

The vault is the same size as the seat above—15 inches by three feet, and has a solid foundation of brick which extends two feet under ground, and is laid with water-lime. From the ground-level the wall is laid with brick, with an opening on the back side at the bottom, ten inches high, covered by a lattice screen hung on hinges, so as to open upward. A box of pine plank, made to just fit the bottom of the vault, is nine inches high; this is water-tight, and prevents any possible leakage, so that the mason-work below is kept dry, and is in no danger of freezing and cracking. This may be unnecessary; but where health is at stake, it is better to make assurance doubly sure. Typhoid fever is not rare, even in the country. It is thought that it comes from pollution of drinking-water.

The seat, and the special covers to each of its two openings, all hinge at the back, and so can be raised up where they will remain till put down. This makes a neat and convenient gentleman's water-closet, and makes it easy and neat to add road-dust whenever the place is used. At one end of the seat is the door to the dry-dust closet, which is made quite large, and with a slanting floor, so that the dry earth is always at the door. The space just back of the door has a fender, so that the dust will not run out when the door is opened, and this also gives a nice place for the shovel which is used to apply the dry earth. A door outside, nine feet from the ground, enables dry earth to be shoveled into the earth-bin from a cart with ease. A carpet, two or three neatly framed pictures, and a printed sentence on the door which says, " Never leave this room without adding dry earth," makes the neatly plastered room quite a contrast to most places of the kind. Need I say that our children have never thought to mark on the walls, although they have had lead-pencils ever since they could use them? We have never been annoyed with any offensive odor in the wood-shed, even in mid-summer. Indeed, the very location makes it imperative to use such caution that the place will ever be sweet, and so insure thought and painstaking. Two good loads of road dust suffices for the year. Shoveling out the contents, and drawing the useful fertilizer to the fields or garden is not at all offensive if the dry earth has been added properly.

A recent writer in the *New-York Tribune* suggests an improvement to the above. He places a large heavy tin pail under each opening in the seat. This makes it necessary to empty often; but the work is easy, and there is no possible chance to contaminate the soil. In winter, a little hot water poured on to the outside of the pails will loosen the frozen contents. A. J. COOK.

Agricultural College, Mich., Apr. 20, 1886.

Many thanks, friend Cook, for your excellent report and suggestions. I agree, that, as you manage it, nothing can be nicer or more convenient. It was the sight of that pleasant little room that opened my eyes to the fact that it was possible, with so little expense, to make such a very great improvement in these adjuncts to our homes. When I think of those children with their lead-pencils, I feel like saying, " May God bless them, and help them to grow up just such useful members of society as their father and mother are." We gathered road dust one year here at the factory; but we found it quite heavy to shovel and draw around, and I am afraid we got weary in well doing. Somebody has suggested that ashes from the kitchen-stove will do very well when road dust is not at hand. They are lighter to handle, and many times easier of access, even if the resulting fertilizer should *not* be quite according to the teachings of modern science.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

MEDINA, MAY 1, 1886.

> Whosoever drinketh of the water that I shall give him shall never thirst; but the water that I shall give him shall be in him a well of water springing up into everlasting life.—JOHN 4:14.

WE should like reports of the new perforated honey-boards, now that the price is so low as to be in reach of every one.

COMB HONEY AT A BARGAIN.

As the lot of comb honey mentioned on page 329 does not seem to move off very rapidly, we make the price 13 instead of 14 cts. Discounts same as before.

20,000 SECTIONS SHIPPED PER DAY.

THE foreman of the freight department has just informed me that we are shipping sections at the rate of twenty thousand per day, and sometimes as many as 100 hives. Does it not look, friends, as if our goods are giving satisfaction, and that every one is getting ready for a big run of honey?

ANOTHER BEE-JOURNAL.

FROM E. H. Cook, Andover, Ct., comes now a little pamphlet, called *The Bee-Hive*, published every other month, at the insignificant price of 20 cts. a year. Friend Cook is good for all he promises, or, at least, always has been; and as the initial number is worth the 20 cts., without question, we don't see why it shouldn't have a good circulation.

THE AUSTRALIAN BEE-MANUAL.

WE are just in receipt of a new book on bees, bearing the above caption, by Isaac Hopkins, Matamata, Auckland, New Zealand. It is a large work, of 330 pages, and illustrated with 143 engravings. The author seems to take up very thoroughly the scientific and physiological structure of the bee, at the same time setting forth a full elucidation of the practical management and care of an apiary. We presume it is written for and adapted to the climate of Australia, and we are glad to note that the friends of that far-off land have made such progress. We have not had time to examine into the soundness of the author's views on the various subjects, but may give a more extended review of the same soon.

THE PRESENT SEASON.

BEES, as a rule, wintered very successfully, and the month of April has been so far, perhaps, one of the finest for our industry ever known, especially in the Northern States. Apple-trees are now in bloom this 27th day of April, and honey is coming from a great many sources at a pretty fair rate. Bees and queens ought to be plentiful and cheap, if conditions continue to be as favorable as they now are.

HONEY FROM THE WHITE ASH.

On Easter eve, April 25, while passing along the street, toward sundown, my attention was called by such a loud roaring of bees that I commenced an investigation. It came from a tree in a neighbor's yard, and the roar was so loud that I heard it the width of a wide street. It was a large, beautiful, round-topped white ash, and there were more bees on the blossoms than I perhaps ever saw on any other tree at a time. I do not remember to have ever noticed bees on this kind of forest-tree before, and it illustrates what has come up so many times, that almost any tree or plant may yield honey profusely when it so happens that all the conditions are just right for the secretion.

APICULTURE IN CORNELL UNIVERSITY.

We are pleased to learn that Prof. J. Henry Comstock, Professor of Entomology and General Invertebrate Zoology of Cornell University, is making an effort to start a department of apiculture in the college. We presume it is the intention to make it a part of the course of study, under the general head of agriculture. It is to be observed, that Prof. Comstock occupies a position relatively the same as Prof. Cook of the Michigan Agricultural College. With three such able men as Profs. Cook, Comstock, and McLain, the latter of Aurora, Ill., great things are in store for us. Surely the science of apiculture, as indeed a science it is, will not lack for a good scientific backing.

A GOOD COMPOUND MICROSCOPE, FOR A SMALL AMOUNT OF MONEY, FOR BEE-KEEPERS.

We have just received a new lot of microscopes, such as we have been advertising in our price list, for the examination of the eye, sting, etc., of the bee. They are remarkably well finished, and their adjustment is perfect, and they are quite superior to those we have formerly advertised and sold at $2.00. The lenses of these insruments, however, are very clear, and are mounted after the American pattern, which is decidedly a great improvement. I have no hesitation in saying, that, for certain kinds of work, they compare very favorably with the forty or fifty dollar instruments. With it most specimens from the bee will appear to good advantage. It will reveal a wonder to those desiring to look into the intricate mechanism of the bee; and to one who can not afford to invest a very large amount, this, I feel sure, will give excellent satisfaction. Price, complete, packed in a neat mahogany box with dissecting forceps, two glass slips, and two mounted specimens, $2.00; by mail, 15 cents additional. Extra mounted specimens from the bee will be 15 cents each, or $1.50 for a series of a whole dozen.

IN SEASON AND OUT OF SEASON.

In spite of what I said last number about dropping, for the present, the consideration of the wintering problem, quite a number of long articles have since come in on the subject. I know it is quite natural for us to discuss the question just after winter has past, when we feel full of good ideas. No doubt your ideas *are* good, friends, if you have been successful; but just hold 'em in, and jot 'em down in your note-book. When the time comes for us to be thinking about putting our bees in condition for winter, by all means let us have them then. If we discuss wintering during the honey-flow, when our minds are taken up with other things, even if we do read the articles we shall be likely to forget the good hints that they contain. Meantime, as far as possible, let us try to be just in advance of the season. When we are running for comb honey, we all want to know whether any one has discovered a better method than our own. The same may be said of queen-rearing, robbing, and wintering in *its* turn. Several of our contributors are careful to carry out the spirit of the above. Among them I might mention friends Doolittle, Cook, Miller, France, and others.

PERFORATED TIN HONEY-BOARDS.

Several have inquired why we do not make perforated *tin* honey-boards, giving, as a reason, that tin was cheaper. After several experiments with our perforating-machine we have been forced to abandon it as impracticable. We can perforate the tin, but it does not give very good satisfaction. When it leaves the machine it is considerably bowed up in the middle, rendering it unfit for the purposes of a honey-board. The zinc, on the contrary, comes out smooth. At present prices, tin is only a trifle cheaper than the zinc; but as the latter is much more rigid, and makes a cleaner cut, and the former is harder on the dies, and more expensive to perforate, we must give our preference decidedly in favor of the zinc, not only because it is much more satisfactory, but cheaper when cut. However, the tin will answer every purpose when used for the perforated tin separators; i. e., with the oblong hole. Prices, as thus perforated, will be $2.50 per 100, or $22.50 per 1000. By the way,

SHEETS OF PERFORATED ZINC ARE STILL LOWER.

When we were constructing our perforating-machine our intention was to use sheets of zinc 28×96 inches, just enough for 10 honey-boards. When we came to order the zinc we could not at first get sheets longer than 7 ft. We have now succeeded in getting sheets 8 ft. long, as first intended, and the price of these sheets will be $1.50 each; 5 % off for 2 or more sheets; 10 % off for 10 or more. This is the same price as was quoted on the sheets 7 ft. long, but the sheet contains 2⅓ ft. more of the zinc.

UNBOUND PERFORATED ZINC HONEY-BOARDS, CHEAP.

Later.—Our perforating-machine has just learned a new trick, or, rather, our machinists have "tumbled" to a new idea. Said they, "Why can't we make perforated honey-boards without the tin lining, leaving a margin of unperforated zinc instead?" They accomplished this by taking out five of the punches in the center of the great jaws; and by stopping the machine at the proper intervals there will be a good margin around each honey-board. We next take the whole sheet to the squaring-shears, and slice up our honey-boards by the dozen. These boards will not be as rigid as the tin-lined honey-boards, it is true; but might it not be desirable to lift up one end in taking it off the hive, somewhat as you do an enameled cloth? These unbound perforated honey-boards will yield considerably without being bent up. Perhaps there are some who would prefer them to the tin-lined. We can furnish the plain, or unbound honey-boards at 16 cts. each; 10 for $1.50; or 100 for $14.00.

ORDERING HEAVY GOODS BY EXPRESS.

IT seems as if there were more orders this season than ever before for exceedingly heavy goods, and goods that, from the nature of them, we think can not be wanted immediately, to go by express. We have supposed one reason for this is the delays on goods ordered by freight, in consequence of the strikes; but it would be a very great relief to us indeed if our customers would make some explanation in ordering goods to go by express that usually go by freight. Suppose you add to the bottom of your letter something like the following: "I have ordered the above hives in the flat to go by express, knowing that the charges on them will be tremendous. But I would rather pay excessive charges than to stand a chance of not getting them at once." We have for years been in the habit of disobeying orders to the extent of sending goods by freight, even though ordered by express, when we were quite sure the express charges would amount to more than the value of the goods. But it is always risky business to disobey orders. As a rule, we get thanks for using our own judgment in such matters; but sometimes we get a fearful blowing-up, with a bill of damages besides. In the latter case, the man knew what he wanted, and had special reasons for ordering his goods by express; but he omitted to add just two or three little words, telling us he was prepared to pay the charges, whatever they were. Sometimes it may pay a man to order his sections and hives by express, even in the month of April, providing he lives in Florida or Texas, or away south where the bees are swarming; but if a man in York State or Michigan should order sections or hives in the flat, by *express*, we should either say he was not well posted, or else he was out of his head. Now, will you not help us by a little explanation, when you have made up your mind to incur the excessive charges on bulky goods by express, rather than wait for them by freight?

A NEW BOOK BY FRIEND T. B. TERRY.

OUR compositors are now hard at work on this book, entitled, "Winter Care of Horses and Cattle; The Most Humane and Profitable Treatment," and the first 16 pages are already in print. We think the book will be received with more favor than any thing else that has yet appeared from the pen of friend Terry. His plea for kindness and good care toward our domestic animals ranks him side by side with friend Henry Bergh; and friend Terry explains to us how it is that humane treatment puts money into the pockets of the owners of stock. The price will be, bound in paper, 50 cts.; in cloth, 75 cts. If wanted by mail, add 3 cts. postage for the former, and 8 cts. for the latter. We expect to have it ready about July 4th.

THE number of our subscribers is slowly increasing. At this date we have 5522.

LARGE QUANTITIES OF HONEY FROM THE SWAMP-OAK.

THE HONEY AS FINE AS BASSWOOD.

BEES are doing finely here; and of over 200 colonies in this vicinity last fall, there is a loss of only three. All were wintered on summer stands, principally in chaff hives. Bees at this date are gathering large quantities of honey from the swamp-oak. I noticed this morning that they were very busy on a large oak, and upon closer investigation I found that there was a minute drop of honey, clear as crystal, and very thick, adhering to each leaf-bud. Of course, the oak has not yet leaved out, but the buds are swelling, and show a slight green color, and upon each bud was the drop of honey. I took my knife and gathered enough to make quite a large drop, and tasted it, and it had no taste of honey-*dew* or aphis secretion, and in thickness and color it equals basswood, and certainly I never saw *any* basswood produce as much honey as the oak I have mentioned. If it is the work of the aphides, they are so very small that they can not be seen with the naked eye, for I looked very closely, and had others look, and even climbed the tree, and made a very close examination, but failed to find any thing indicative of aphides. The bees are breeding up very fast as the result, and yet do not use nearly all they gather, and in the combs it shows very clear and thick. Now, does the oak always yield honey, and am I just finding it out, or is it only in rare instances that it does so? Will the editor, Prof. Cook, or somebody else, express an opinion? We are very thankful, anyhow, as it comes when most needed; and to see the sheets of solid brood in our hives has a tendency to make a fellow feel happy about his bees, if nothing more.

M. W. SHEPHERD.

Rochester, Lorain Co., O., Apr. 22, 1886.

Friend S., the honey you mention from the oak is probably the natural secretion. It has been written about for years past, although I do not remember that we have had a report before of honey from oak-trees so near our own locality. Neither do I remember of hearing other reports, mentioning that honey was secreted before the tree was in leaf. Former reports mentioned that honey was secreted from the buds just before they opened to produce a blossom. If, as you say, each bud that would produce a leaf yields honey, the matter is still more curious. I am glad to hear so good a report on wintering. Is there sufficient honey from the oak to induce comb-building? and do you find it only on the swamp-oak?

GOOD'S NEW
REVERSIBLE HIVE
all complete, well painted, for $3.00. Sections very low, No. 1, 4¼x4¼x1⅞ or 1¾, at $4.00 per 1000.

WANTED.—To exchange, tested Italian queens, reared last fall, at $2.00 each, for thin fdn., not less than 10 sq. ft. to the pound.
9tfdb G. D. BLACK, Brandon, Iowa.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I shall have a limited number of hybrid queens for sale during May, June, and July, at 50c each.
LOUIS WERNER, Edwardsville, Ill.

Friends, I have 5 black queens that I will take 25c each for; and 6 Hybrid queens for which I will take 50c each during the latter part of this month.
A. E. JOHNSON, Clarkton, N. C.

W. P. Davis, of Goodman, N. C., will sell hybrid queens during the months of May and June, three for one dollar. Parties return same at my expense, if not satisfied. W. P. DAVIS.

Two black queens at 25c each; 3 hybrids at 40c, and about 10 mismated queens at 50c each.
G. D. BLACK, Brandon, Iowa.

I have three black queens I wish to sell, 35 cts. each. Will be ready the first week in May.
F. P. HISH, Henton, Shelby Co., Ills.

For sale, 12 young mismated Italian queens, G. M. Doolittle stock; wings all clipped. Price 50c each. Will ship at once. L. L. HEARN,
Frenchville, Mercer Co., West Va.

BINGHAM SMOKERS LAST AND PLEASE.

BORODINO, N. Y., Aug. 15, 1882.

All summer long it has been "which and t'other" with me and the Cyprian colony of bees I have—but at last I am *boss;* Bingham's Conqueror Smoker did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham. G. M. DOOLITTLE.

INDEPENDENCE, CAL., Jan. 2, 1886.

Messrs. Bingham & Hetherington:—Dear Sirs:—

The "Doctor" came to hand last night in good order. "It is a Daisy." Won't the little pets wink their eyes when they get some of his medicine? I have one of your "Large" smokers, which has been in use six years.

Respectfully yours, WM. MUTH-RASMUSSEN.

Bingham Smokers and Knives sent per mail, postpaid, at 65 cts. to $2.00. Send for free circular to
51fd **BINGHAM & HETHERINGTON, ABRONIA, MICH.**

STANLEY'S
AUTOMATIC HONEY-EXTRACTOR.

The only self-reversing Honey-Extractor known. Will do double the amount of work of any other extractor. Send for new circular, just out April 1st. Californians, send to Baker & Barnard, San Buenaventura, Ventura Co., Cal. Canadians, send to E. L. Goold & Co., Brantford, Ont., Can.

All others, address G. W. STANLEY,
8tfdb Wyoming, N. Y.

Californians.—Good live men to act as sub-agents in the different counties of Cal. Parties wishing to become agents, or to manufacture the Automatic extractor can address Baker & Barnard, San Buenaventura, Cal., or G. W. Stanley, Wyoming, N. Y. This is a good chance for those who want to make and sell our machines.

STANLEY'S DOLLAR SMOKER.

A large strong bellows Smoker, with 3 in. barrel, and equal to any smoker in the market, for only $1.00, or $1.25 by mail. Can be sent immediately.

SPECIAL OFFER UNTIL MAY 25TH.

Every person who purchases a 4-frame Automatic Honey-Extractor before May 25th, and sends cash with order, will receive a smoker *free*.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have about one dozen hybrid queens for sale at 25c each. Good and prolific. M. BROERS,
Gonzales, Gonzales Co., Texas.

Ark. Brown and hybrid queens 20 to 40 cts. each.
F. C MORROW, Wallaceburg, Ark.

Black queens, 25c until June.
WALTER B. FISHER, Uvalde, Uvalde Co., Texas.

Hybrid queens at 40 cts. from May 20th.
J. G. COBB, Mount Cobb, Pa.

75 black and a few hybrid queens left for sale, at 25 and 35c each. All clipped. Safe arrival guaranteed by return mail. L. T. AYERS,
Box 175, Kankakee, Kankakee Co., Ills.

I have some 10 or 12 black and hybrid queens to sell, after the 18th inst., at 25 and 35c each.
J. C. ZIMMERMAN, Wabash, Wabash Co., Ind.

Black and hybrid queens for sale at the usual rates. GEO. D. RAUDENBUSH, Reading, Pa. 10d

Hybrid queens must go. In order to rid my apiaries of the last vestige of black blood, I offer 6 good hybrid queens (all that I have) at 40 cts. each, or $2 00 for the lot. Speak quick, for I will kill them if not called for soon. Address
J. C. BOWMAN, North Lima, Mahoning Co., Ohio.

F. HOLTKE'S 3-FRAME NUCLEI, WITH $1.00 QUEEN, FOR ONLY $2.00!

Three-frame nuclei, with $1.00 queen, from 15th of May on, $2.00. Combs built in Simplicity frames, and well stocked with bees and brood. 10-11-13d
Fred'k Holtke, Carlstadt, Bergen Co., N. J.

Batchelder's Drone and Queen Trap

Is the only one made that does not hinder the bees in their work. Send 85 cents for sample. Send for circular, and see what A. I. Root says about it.
10tfdb **J. A. BATCHELDER, Keene, N. H.**

SECTIONS

AT HARD-PAN PRICES. V-groove or square cut. Samples free; also chaff hives, Root's pattern; Dunham comb-foundation and apiarian supplies of all kinds. Write, stating what you want, and I will quote you rock-bottom prices. Circular free. 8tfdb **EZRA BAER, Dixon, Lee Co., Illinois.**

PURE ✳ ITALIANS ✳ EXCLUSIVELY.

STOP, ✳ READ, ✳ AND ✳ ORDER.

Having determined to devote my time and attention exclusively to the production of pure Italian bees and queens, during the season of 1886, I offer, in order to reduce stock, **50 Choice Colonies of Pure Italians** in 10 Langstroth frames, guaranteed to contain at least 4 full frames of brood and 4 lbs. of bees in new chaff hive, at $10.00 each. I append my prices for the season.

My terms are cash with the order. First orders will be filled first. I will refund money at any time a customer may become dissatisfied with waiting.

My methods: One kind, and the best of that kind. Nothing except tested queens sold at any price. I will send one-year-old queens until stock is exhausted, and then this season's hatch. I will commence to send, about May 1st.

1 tested queen	$1 00
1 pound of bees	1 00
1 frame of brood and bees	1 00

1-frame nucleus, tested queen	$2 00
2 " " " "	3 00
3 " " " "	4 00
4 " " " "	5 00

In lots of 5, five per cent discount; in lots of 10, ten per cent discount. In lots of 10 or more nuclei or pounds of bees, I will pay express charges for the first 1000 miles. Now remember, I guarantee safe arrival and absolute satisfaction in all cases. Sample of live workers free by mail. Capacity, 25 queens per day after May 1st.

THOMAS HORN,
8tfdb BOX 691, SHERBURNE, CHENANGO CO., N. Y.

KENWARD-HALL APIARY.

Thanking our friends for their large orders, March and April, we assure them that we shall try to merit all orders in the future. 200 nuclei. Our queens imported by ourselves. Price $1 00; ½ doz., $5.00; 1 doz , $10 00. Tested, $2.00 and $3.00. Special rates to dealers.

J. W. K. SHAW & CO.,
8-10db **Loreauville, Iberia Parish, La.**

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—Demand for all grades light, with a very light stock of comb in the city. Extracted dull and very low. With the low freights from California, our trade has been well supplied.

One-pound sections, choice,	16
“ “ “ dark,	12@14
Two “ “ choice,	12@14
“ “ “ dark,	9@10

Extracted, from 3½ to 6 cents. *Beeswax*, 23c.
May 11, 1886. CLEMONS, CLOON & CO.,
Cor. 4th & Walnut St's., Kansas City, Mo.

CHICAGO.—*Honey.*—The supply of comb honey is fully up to demand, unless it is for fancy one-pound sections (without glass), which brings 15@16c. Two-pound sections, 10@12c, slow of sale. The demand for extracted is very light, at unchanged prices. *Beeswax*, in larger supply at 23c. R. A. BURNETT,
May 10, 1886. 161 S. Water St., Chicago, Ill.

CINCINNATI.—*Honey.*—There is no new feature in the market. Demand fair for extracted honey for table use, but exceedingly dull from manufacturers. Prices are unchanged and nominal. Prices of comb honey are nominal, and but little on the market. We sell at 14@15c a lb. for choice, in the jobbing way. *Beeswax.*—There is a good home demand. Good to choice yellow brings 20@22c. on arrival.
May 11, 1886. C. F. MUTH & SON,
S. E. Cor. Freeman and Central Avenues,
Cincinnati, Ohio.

ST. LOUIS.—*Honey*.—We have no features to note in our honey market, except dullness. Demand is very light, prices quotably unchanged—any way, not improved. W. T. ANDERSON & CO.,
May 11, 1886. 104 N. 2d. St., St. Louis, Mo.

MILWAUKEE.—*Honey.*—Market here seems quite dull; the demand is very limited, and the supply not very large. Values continue unchanged.

Choice white 1-lb. sections,	17@18
“ “ 2-lb. “	16@17
“ dark 2-lb. “	15@16
Extracted, in kegs or tin, white,	8@8½
“ “ “ dark,	6@7

Beeswax, 25c. A. V. BISHOP,
May 11, 1886. 142 W. Water St., Milwaukee, Wis.

DETROIT.—*Honey.*—There is no honey left in commission houses, and but little in the hands of retail dealers. New honey will find the market bare. Best comb, in 1-lb. boxes, 14c. *Beeswax*, scarce @25c.
May 11, 1886. M. H. HUNT,
Bell Branch, Mich.

CLEVELAND.—*Honey.*—Our market continues good for best 1-lb. unglassed sections, which bring 14@15 cts. readily on arrival, 2-lbs. are dull at 12@13 cts. Glassed sections sell slowly at 12c. Extracted, 7@8. *Beeswax*, scarce at 25@28. A. C. KENDEL,
May 8, 1886. 115 Ontario St., Cleveland, Ohio.

BOSTON.—*Honey.*—No change in price of honey. Sales very light. BLAKE & RIPLEY,
May 11, 1886. 57 Chatham St., Boston, Mass.

HONEY-JARS.
Buckets and Tumblers of Crystal Glass
CORKS, TIN-FOIL CAPS, ETC.
Best Quality, at Lowest Prices.
Address for Prices, etc., **TYGARD SONS,**
10d **2119 S. Jane St., Pittsburg, Pa.**

QUEENS.
I have them, bred from a best selected queen of Root's importation, 90 cts. each; 6 for $4.50. I can give all orders immediate attention, and ship by return mail. Send postal for dozen rates.
10tfdb **B. T. BLEASDALE,**
596 Woodland Ave., Cleveland, Ohio.

HILL-SIDE APIARY.
ITALIAN BEES AND QUEENS, BEES BY THE POUND, NUCLEUS, OR FULL COLONY.
Send for Circular to
W. B. COGGESHALL, Supt.,
Summit, Union Co., N. J.

For Sale. A bargain for some one. 320 acres of land in Reynolds Co., Mo., only 12 or 15 miles from Iron Mountain R. R. Well covered with pine timber, never having had a tree cut on it. Taxes less than $5.00 per year. Will sell for $10.00 per acre. 10d J. S. WARNER, MEDINA, O.

Stanley's AUTOMATIC HONEY-EXTRACTOR AND DOLLAR SMOKER.
Special Offer. See Advertisement in another column.

FOUNDATION, 6 SHEETS FOR L. FRAME, 35C. PER LB.
W. T. LYONS, Decherd, Tenn.

LOW COST HOUSES
HOW TO BUILD THEM
A large Atlas, giving cuts and full descriptions of 40 *desirable* **modern houses, costing from $400 up to $6,000.** *Profusely illustrating every detail* **and many original ideas. Houses adapted to all climates described. The latest, best, and only cheap work published. Sent by mail, postpaid for 50c. in stamps. FRANKLIN NEWS CO., PHILADA**

EXPRESS PREPAID upon EGGS FOR HATCHING from our premium stock of Fowls. Send for price list. Satisfaction guaranteed. Ref. A. I. Root.
9d BOSTWICK & ASHLEY, Medina, Ohio.
P.S.—4 in. German Carp, $5.00 per 100, F. O. B. here.

CONVENTION NOTICES.

The Madison County (N. Y.) Bee-Keepers' Association will hold a semi-annual meeting in the parlors of the Eagle Hotel at Oneida, N. Y., on Wednesday, May 26. The meeting will be called at 10 o'clock A. M., sharp. All interested in bees or honey are invited to attend. All apicultural goods sent for exhibition will be carefully looked after by the officers of the association. F. S. SMITH, Pres.

The date for the next meeting of the N. A. B. A. has been fixed for the 12, 13, and 14 of October next.
Indianapolis, Ind. F. L. DOUGHERTY, Sec.

CIRCULARS RECEIVED.

The following have sent us their price lists:

J. B. Batchelder, Keene, N. H., an advertising sheet of the Batchelder drone-trap.

J. J. Hulbert, Lyndon, Ill., a 14-page circular of bee-supplies in general.

Thos. L Thornton, Dividing Ridge, Ky., a 6-page price list of apiarian supplies.

J. R. Landes, Albion, Ohio, a 4-page circular—specialty, bees, queens, and poultry.

Will Ellis, St. Davids, Ont., Can., apiarian implements and a specialty of fine comb fdn. Will Ellis has obtained the first prize on foundation at the Lindon Western Fair, and first and second prize on foundation an the Toronto Industrial Exhibition. This fdn. was made from one of our make of mills, and the friends w.l. do well to bear this in mind when in need of a comb-mill.

I am being asked my opinion of the new circulars Mrs. Cotton is again sending out quite plentifully. The statements she makes, and the prices she charges for the goods she sends out, would, in my opinion, forbid her being classed with our regular supply-dealers, to say nothing of the strings of complaints against her that have filled our bee-journals for years past.

REDUCTION IN THE PRICE OF BEES AND QUEENS FOR THE MONTH OF JUNE.

Just before going to press.—The season is so extremely favorable for the production of bees and queens that we have decided, besides the offer mentioned on page 426, to make the prices of bees and queens, after the first of June, at July prices.

GLEANINGS IN BEE CULTURE.

DEVOTED TO BEES, HONEY & HOME INTERESTS.

Vol. XIV. MAY 15, 1886. No. 10.

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00; 10 or more, 75 cts. each. Single Number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent TO ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

JAMES HEDDON ON THAT WINTERING PROBLEM.

EXPERIMENTS IN FAVOR OF SUGAR STORES.

IT will be remembered that I have all along declared that the prime cause of our great winter enemy, bee-diarrhea, was concealed in their food. Well, through the persuasion of Mr. Barber and other successful bee-keepers I had almost made up my mind that possibly I was not altogether right about the matter, and that temperature was about all we need to look to; at least, I hoped that this easy solution of the difficulty might prove true. Last fall I prepared for extensive tests regarding the matter, and now I will state facts relative to my experiments during the past two winters, and let the reader draw his own conclusions to suit his reason and understanding.

Perhaps the reader will remember, that in the fall of 1884 I placed in a damp cellar 91 colonies, 73 of which had no natural stores of any sort (not a cell of bee-bread), they having clear sugar syrup fed into clean dry combs, while the other 18 had a part all natural stores, and a part a mixture of natural and artificial. The cellar was very damp—so much so that mold and pools of water could be seen about nearly every hive. About one-third of the colonies had upward ventilation; the others, only entrance ventilation. The cellar was allowed to become very cold. For weeks the temperature stood as low as 20°. Nearly every one of the 18 colonies on natural stores had bee-diarrhea, and the 73 on pure syrup came out, after a confinement of 151 days, without any fecal accumulations whatever. When they had their first flight, not a thing—not even water—could be seen coming from them—not a spot on any of the white hives. Here was cold and humidity, but no fecal accumulations. From one of the sick colonies (dead with bee-diarrhea) I took a sample of the excreta, and sent it to Prof. Cook for chemical analysis. I also inclosed some pollen from the comb contained in the frame from whose top bar I took the excreta. The professor answered as follows: "I have subjected the pollen to a very careful examination with a one-sixth objective. I find several kinds of pollen grains, two of which are by far the most common. One is oval, rather pointed at the ends, with a longitudinal slit and numerous projections; the other is globular, and thickly set with projections much like those in the other. I then studied the excreta; and had some one else made the change, I should have stoutly maintained that the objects were the same that I had just studied. The kinds of pollen were exactly the same in style and markings. The pollen you sent had been liberally appropriated by the bees whose excreta you sent."

Last fall I placed in a filled-wall, above-ground repository (room 11×7×18 feet) 150 colonies, with stores part natural, and part syrup. This house was kept at a temperature between 45 and 50°, and no signs of the disease appeared till late in winter, and, when taken out, no less than 25 to 30 colonies had diarrhea to a greater or lesser extent. For over three weeks, at one time, I maintained the temperature by closing the room as tightly as good carpenter-work and packing could make it; and during all this dearth of "fresh air," the bees remained quiet and in apparently perfect health. Here at home I placed 300 colonies in two cellars, one damp and the other very dry, the same as at Glenwood. We endeavored to keep up the temperture by tightly closing the rooms in the coldest weather, and we did so with the new cellar; but with the old one we failed, as at the back end there was a hole between the old boards that we overlooked, and never should have found, but that we caught it melting holes through the snow on the outside. Nevertheless, the temperature of both cellars never went below 45° nor above about 50°, and all was quiet, and no odor of diarrhea till near spring, and then the disease began to appear, and was rather worse in each cellar than at Glenwood, in the house.

Most of the colonies here were trusted to natural and part natural stores and high temperature; and none, except the few upon *all* artificial stores, came through without *any* fecal accumulations. It has well been said, that with honey at the present low price and slow sale, the purchase of 20 or 30 barrels of sugar, when 20,000 lbs. of the nicest honey is on hand, is almost impracticable, and this is the reason that I trusted most of my colonies to all or part natural stores. I must say that I am disappointed to find that, under no conditions, are we at all times sure of wintering one-half of our colonies with natural stores. It may be that in many localities this can always be done, but I can't do it here. This much is solved: I can winter any colony with certainty; but to do so I must not only keep up a 45 to 50° temperature, but see that their only food is pure cane-sugar syrup properly prepared and fed. My last winter's experiments fail to attach any importance to ventilation and humidity.

I had two colonies on natural stores, thoroughly packed, outdoors, and one of them died with the diarrhea. I did not expect this, but find the pollen theory too true in my locality. I did not hope to bring my bees through in *perfect* condition on natural stores, but I hoped to bring all through in condition to make good working colonies by the time clover bloomed; but I must own, that in this I was mistaken. Friend Barber's plan won't do here. I have just sent two specimens of the diarrhetic excreta to Professor Cook, and here is his report:

"The thick feces is loaded with pollen of various kinds, and largely insoluble in water. It has also many spherical fungi. The other, also, has much pollen, but less. It also has the spherical bacteria, or fungi, and, in addition, some forms which are chain-like. This is more soluble than the other; but after boiling for some time in water there is quite a residue that is insoluble."

The above are the facts, and all may draw their own conclusions. It seems to me they pretty well refute the opinions of Dr. Joslin and Father Quinby, as recorded by Mr. Hutchinson, on pages 249 and 250. JAMES HEDDON.

Dowagiac, Mich., May, 1886.

BEES CAPPING THEIR CELLS WITH COTTON BATTING.

DO BEES SEND OUT SCOUTS BEFORE SWARMING?

I HAVE some quilts made of sheeting and cotton batting. I noticed, a few days since, at the entrance of one hive some of the filling of one quilt, which had been carried out. I opened the hive, raised out the brood-combs, and found they had been using that cotton for capping some of their brood. Some of the young bees had nothing over their heads (and those that had no heads formed), but simply fine bits of cotton stretched across the cells in many ways, and I could look through the network covering and see the little fellows, like looking through a sieve. There was one patch about two inches square with no capping except cotton batting. You may say this was moth-webs; but I say no, not the work of any thing but the bees capping their brood.

Last summer I was doing some carpenter work for a man about a mile from where I live, about the last days of June. As I had lost most of my bees the winter before, I took what work I could get, as the 20 weak colonies I had left did not require much time. One day my wife came to where I was at work and said my bees had swarmed. "Well," said I, "where did they go?"

"Why, they went into a hive," she said.

I said, "Do you know which hive they went into?"

"Yes," she replied, "I marked the hive with a stone."

"Well, do you know which hive they came out of?"

"No," she said; "I did not see them until they were all flying."

When I went home in the evening I found they had entered a hive with combs in which the bees had died the previous winter; and when I examined I found them to be hybrid Italians, very cross, and I did not have a hybrid in the yard. There were also more bees in that swarm than I had in any two of my hives. The next week I noticed a great many black bees flying around my empty hives, and at five o'clock in the evening a large swarm of black bees came and went into another of my hives. I saw them come.

10—MONT. WYRICK, 20—46.

Cascade, Ia., Apr. 28, 1886.

Something of this kind, about bees capping cells with fibrous material, has been brought up before, and I presume there is no question but that the bees do, under some circumstances, use fibrous material. The cappings of the brood-cells are not wax, in any case. The fact you furnish about stray swarms of bees occupying your hives is also valuable; it seems to me as if it might pay to have hives fixed just right, ready for such truant swarms.

HEATING WATER AT DIFFERENT DEPTHS IN A CAN.

THE FEASIBILITY OF BOILING EGGS FROM THE SURFACE OF THE WATER.

I HAVE been a reader of your paper for the last year, and find it very interesting and instructive. I noticed a sketch in March 15th issue, over the signature of Ernest R. Root, "Experiments with Wax-extractor," in which the boiling-point, 212°, is reached. He thinks that eggs boiled by the sun are quite probable. I think he will have to boil them very near the top. I was attending a farmers' meeting in our town some years since. The question came up concerning cooling milk from the bottom. Some thought it could be cooled to the depth of a foot or more; when Dr. Marquis, one of our townsmen, who, by the way, had been experimenting with a pan he invented, asked the club over to his store to see what he could do. His pan was sixteen inches deep, with three faucets—the first, four inches from the bottom; second, four inches from the first; third, four inches from the second. He first asked one of the gentlemen to try the water in the pan. He found it alike in all the faucets—the same temperature as the air in the room. He then attached his cooling apparatus (which is a hollow tube) to a force-pump in the cistern, and lowered it to the bottom of the pan. His next move was to attach his heating apparatus to a steam-gauge, and lower it in the pan to the first faucet from the top, this likewise a hollow cylinder. He then stepped back in the store and got some eggs and laid a couple on the heating cylinder and dropped one to the bottom of the pan. He then told his servant to pump the water passing through the cylinder at the bottom, and back to the cistern. At the same time he turned on steam at the top, and in a very short time the water at the top was boiling rapidly. He kept both heat and cold going perhaps ten minutes, then he asked the gentleman to draw some water from the middle faucet and try it. It had not changed in temperature from where it was at on the start. He then raised his heating-cylinder and presented the ladies a couple of boiled eggs. He next tried to remove his cooler from the bottom, and found it frozen fast to the bottom of the pan. When he got it loose he brought up the egg, and at least one-half inch of blue ice. The egg was frozen open. He then reversed proceedings, putting the cooler at top, dropped some aniline on the cylinder, and commenced pumping; in a very short time the aniline was thoroughly mixed with the water. So I am afraid friend Root will find it up-hill business boiling eggs from the top.

NOYES B. PHETTEPLACE.

Norwich, N. Y., April 8, 1886.

Friend P., the matter you mention is a familiar one in chemistry, and one of the experiments often tried is to pour ether on the surface of water, and set fire to it. While the surface is more than boiling hot, a thermometer just beneath the surface shows no change of temperature, and ice may be in the bottom of the vessel without being melted at all. This very fact is made use of in hot-water arrangements for heating greenhouses. The only way to warm a body of water is to heat it at the bottom and allow the circulation caused by the heat to warm the whole body evenly. If the water containing the eggs to be boiled were placed in a black iron pan, I think the rays of the sun would go down and heat the bottom of the pan enough to warm up the water considerably, but perhaps not enough to make it boil.

ARTIFICIAL PASTURAGE.

DR. C. C. MILLER TALKS TO US ABOUT IT.

THE subject of artificial pasturage is one in which I have been much interested. I have spent upon it some thought and considerable money. Some may think it premature to talk of planting for bees, when millions of acres are yet unoccupied; but the day may come when these shall cease to be unoccupied, and it is well to be prepared in advance for the possible. There are a good many who have so many bees that out-apiaries are established; and for such it would be a great advantage if additional pasturage could be furnished near home at sufficiently low cost to maintain all in the home apiary. Besides, whether many or few bees are kept, there come gaps in the season when there is almost nothing for the bees to do, and it might pay to be at considerable expense to provide artificial pasturage to fill up these gaps. But it must be borne in mind that no one has yet demonstrated, by actual trial, that one or more acres of ground can be planted and occupied permanently by plants from which the honey alone shall pay a profit. Something may be done by scattering seeds on roadsides and waste places. I should like, however, to be able to plant a certain number of acres, and know with some degree of approximation how many colonies could be supported thereby, and know, also, that the honey obtained therefrom would more than pay all expenses. Although my attempts have been failures mostly, it may be of use to others to detail some of them that they may be avoided. One year I planted a quarter-acre of

SUNFLOWERS.

The ground was rich, they were well cultivated, and presented a fine sight when in full bloom; but I never saw any bees on them to amount to any thing. They were of the "Mammoth Russian" variety, and I think possibly the common kind might be better. The Russian produces a large quantity of seeds—perhaps, rather, a quantity of large seeds—but a bushel of common seeds, I should think, would contain about double the amount of meats that the Russian would, because the meat in the Russian seed bears no proportion to the size of the shell.

ALSIKE CLOVER,

Although a great success with some, has been otherwise with me. Sown on clay, several different years, it has generally failed to make a good catch, doing best, however, on low ground. Only one year did I have any success, and then I had an acre that was beautiful. Bees worked on it strong; but after one season of bloom it was gone, root and branch. Last summer there were some fine patches of alsike on ground that had never been sown. I can not think how it got there, unless from seed in manure put on two or three years previously. I have rather settled upon alsike as one of the things I can not succeed with, and yet it is quite possible that, in five years, I may have acres of it flourishing, by knowing just how to manage. I think enough has not been said about the beauty of the alsike blossom. I have never shown it to the lovers of flowers without calling forth warm admiration, and I think many would consider it worth cultivating for its beauty alone.

SPIDER PLANT,

From what little I have tried it, I consider worthless, although producing large quantities of honey, because I know of no way of raising it by the acre without heavy expense.

FLOWERING MAPLES,

Or abutilons, I have had for years. I have seen bees working on them, and have tasted from them the richest drops of nectar I ever tasted directly from any flower; the largest in quantity, also, before ever I saw any mention made of them as honey-plants; but I am rather surprised that time should be taken to talk of such plants as this, poinsettia, or other greenhouse plants. If the smallest slips of these plants were started, by the time they were rooted they could hardly be furnished for two cents each; but a plant just rooted, and planted out as early as our northern seasons will admit, would not be fairly in bloom before frost. Such plants as would be large enough to be of service would need to be much larger, and could hardly be afforded for less than ten cents each. But suppose they could be had for five cents each; and to keep down expense, let us plant them four feet apart each way;

that will require 2722 for an acre, or an outlay of $136 per acre, to be renewed annually at the same expense, as every plant will be killed with the first frost. Is it worth while to talk about setting out such plants in quantity?

FRUIT-BLOSSOMS.

If I were not in a region where fruit is quite plentiful, I think I should certainly try to find what kinds would succeed, and plant of them pretty largely. I have succeeded in having honey stored in sections during apple and cherry bloom but once, and then only by a single extra-strong colony in a few sections. But their influence in urging brood-rearing is so great that Quinby, if I mistake not, said the fruit-bloom decided the season. As to the character of the honey, I have never observed closely enough to make a positive statement, but will rather put it in the form of a question: Is not honey from cherry and plum rather disagreeable, and from apple of fine flavor, resembling the odor of crab apple blossoms? If bees work much on strawberries, I have never been able to observe it; but on raspberries I have seen them work very busily. The only objection is, that they come partly in the time of clover-bloom. C. C. MILLER.

Marengo, Ill., May, 1886.

Friend M., over and over again I recur to this subject, and I do think it is one of the greatest importance. You say no one has yet demonstrated by actual trial that one or more acres of ground can be planted, from which the honey alone will be a profit. This may be so; but even if it is, why not develop the plants where honey alone is not the only source of profit? Bee-keepers should raise buckwheat; or if they can not do that, induce others near them to raise buckwheat, on the plan suggested by G. O. Goodhue, on page 327. Buckwheat, alsike clover, rape, and possibly raspberries, can be worked on this plan; and who knows but that we may, in a few years, raise basswood for the timber and for the honey? My basswood-orchard is getting to be a valuable piece of property, and I should not be surprised if the time would come when the timber would be worth all it cost, to say nothing of the honey. Unless we discover some plant that yields honey in much larger quantities than any thing at present known, it certainly will not pay to raise plants to set them out, as we should have to do with the abutilons and spider plants. I presume you know there is a new plant now under test. See page 391.

LETTER FROM TOUNGOO, BURMAH.

FRIEND BUNKER TELLS US OF THE CONFLICTS AND TRIALS OF THE CHRISTIANS AMONG THE IDOLATERS.

THE goods reached us in good order, with the exception of a few glass pails and tumblers broken. Taking into account that the goods traveled over 12,000 miles, and were shipped and re-shipped several times, this was not bad. The iron-jacket cans, a few of them, got a dash of salt water, and were marred by rust; but this was soon remedied by a dash of japan varnish. We were all very much pleased with the goods, especially Nellie and Ruthie, who soon found clover-heads and other treasures in the grass and straw. These have all been carefully collected for sowing, in the hopes of raising some old home flowers. I had expected to have two Italian swarms of bees to begin with, when the hives ordered of you should arrive; but owing to bad packing, when they reached me both swarms were suffocated. The first swarms to reach Burmah, and suffocated at that! I am much disappointed, but hope for better success next time. I have applied to the government (agricultural office) here for aid to make further experiments in this direction as soon as this war is over.

You have heard through the papers of the annexation of Upper Burmah, and the deposition of King Theebaw, and perhaps you have thought, with many others, if you have thought of the matter at all, "How quickly this Burman Empire has been overthrown, and incorporated with Her Majesty's dominions!" But in fact, the work is far from being completed. We have about 25,000 Christians in Burmah; all the rest are gross idolaters, except, of course, Europeans. Now, the priests of these idolaters, "priests of Baal," have been preaching to their people that King Theebaw, being the head and protector of their religion, has been overcome by the English because of the *prayers* of the native Christians! What a grand admission of the majesty and power of the Christian's God! So these priests say, "Let us kill off all these Christians, and we shall win back our kingdom." As a consequence, these priests have become leaders of war parties, and are scattered all over Upper and Lower Burmah, burning, sacking, and killing all who will not join them. The government police are idolaters, and have joined the insurgents with their arms in many cases.

The Toungoo Mountains run north and south through Shwaygheen and Tavoy Districts, and have a large population of Christian Karens. Of these, 81 churches, or villages, or about 2500 baptized adults, with a large nominal Christian population, are under my care. A band of two thousand or more gathered in the Shwaygheen hills, and attacked the Karen Christian village, killing and burning, especially burning, chapels, and cutting up Bibles and other books. The government could not meet the case, and could supply only a limited number of arms. The people had no leaders but ourselves, their missionaries, so we have been obliged to lead our Christians to war as in the days of the Israelites of old. The Karens, though poorly armed, have met these idolaters, and have fought them, and the slaughter has been great. The native pastors continually quote the wars of the children of Israel as their guide, and woe to the man who seeks plunder. They bring all plunder to the government officers for disposal. Hundreds of these idolaters have been killed, and scores taken prisoners. The leader, a priest of great note, for whose capture the English officers had offered 5000 rupees as a reward, was caught by my Karens a few days ago, under my leading, and is now safely shut up in jail awaiting his trial. His capture reminds me of Sisera of old, for he was captured largely by women, though thought by his followers to be able to appear or disappear, jump a mile, or take upon himself any form he liked, at pleasure. The superstition of these idolaters is marvelous in the extreme. Our troubles are not at an end. The people are in a state of great excitement. We are in the midst of idolaters; we know not what each day has for us, nor when the people will rise. I leave to-morrow to try to raise arms for my people in Rangoon. But few of our Christian Karens have been killed, though many have been wounded. Their escapes have been wonderful, and they say, "Surely God is with us, or we could not escape as we have."

I have spoken of our mission in Toungoo, but these risings are taking place all over the land, and the English are put to the exhibition of their best efforts to overthrow these insurgents. God, however, will smite these idolaters as he did in ancient days. A. BUNKER.

Toungoo, Burmah, Mar. 9, 1886.

Why, friend B., we didn't know before that missionaries had to pass through such ordeals as you mention. It is a terrible thing for a Christian to be obliged to take up firearms, to be used against his fellow-men; but I presume there are circumstances where it can not be avoided, much as we should like to live at peace with all men. We presume you know of the troubles here at home in regard to the strikes, and of the conflicts between labor and capital. May God grant that a Christian spirit may soon prevail, both here at home and in far-away Burmah.

WOMEN AS BEE-KEEPERS.

MRS. AXTELL GIVES US A LITTLE TALK ON THE MATTER.

DEAR MR. EDITOR:—Permit me, through your pages, to give my views as to whether or not women should be deprived of that healthful, ennobling, and remunerative occupation, bee culture. Mr. Heddon has a right to his opinion as to whether it is degrading or not. There are some Christians who think it wrong for women to speak in church; but does it prevent her doing so? To the pure, all things are pure. In this nineteenth century, God is opening doors to us that no man can shut. "Go ye into all the world, and preach the gospel to every creature" might greatly be obeyed if longing, loving hearts knew of the golden mine of the bee-hive. For my part, I wish many more women could be induced to learn the business, especially those daughters who are allowed to sit in the parlor and let mother do the work, or fix up and go down town every afternoon, especially about train time. I am sure, that, were our girls encouraged to spend more of their time at home in such healthful, ennobling, and lucrative employment as caring for bees, there would be many more happy homes, both in the country and in town.

Many an overburdened mother would find it a *real* rest to leave her hot kitchen and don her bee hat, and, slipping on her loose sack sleeves that cover hands securely, and with smoker in hand spend an hour or so with her bees. Who ever nursed trouble over a bee-hive? 'Tis all forgotten; and with glad eyes and delighted heart she delves into its treasures as she gathers up the golden nectar and stores it away for her husband's tea-table.

I say, let woman keep bees all she has a mind to; encourage her in every way possible, and then there will be room enough left for the sterner sex. Why, it almost makes me indignant to think that any one should dare to try to discourage us in so delightful an employment. SARAH J. W. AXTELL.

Roseville, Ill., May, 1886.

The above is about what I should expect of you, my good friend Mrs. A. There is another thing. They can not say that bee culture is all very well for women who are stout and strong, for we all know of your feeble health for so many years. If women feel as I do about getting out into the open air, you surely are right about it; for oftentimes when I go to bed tired at night I feel as if the greatest blessing that I have to thank God for is the fact that I am privileged to get out so much every day under the broad blue sky. By all means, let the women enjoy this blessing too, where they feel inclined to.

THE CHAPMAN HONEY-PLANT.

SOMETHING THAT IS SAID TO BE OF GREAT PROMISE.

AT the convention in Detroit, Mr. Hiram Chapman, of Versailles, N. Y., brought specimens of a plant which he claimed furnished honey in larger quantities than any other known species of the vegetable kingdom. He has grown the plant for several years, and on a sufficiently large scale, so that he was enabled to pass around specimens of comb honey said to have been produced by this plant. He sends us some plants with the following letter:

I ship you to-day fifty Chapman honey-plants which, if properly cultivated, will produce this season seed enough to sow half an acre of ground. It is my custom to transplant before it is so old, and I place it in rows two feet apart. I find, also, that a larger flow of honey is obtained in dry localities. To test the length of the blossoming season, cut back some of the plants as soon as the first balls appear, thus the vitality of the plant will be devoted to the production of other blossoms; the root will throw up strong healthy plants three or four seasons.

I do not intend these as directions, but only as hints to you in your experiments with these plants. I have no hesitation in sending you the plants, for my confidence in you is such that I know you will not take advantage of the situation and use it adversely to my interests; but to relieve yourself from any embarrassment or annoyance which may arise, please acknowledge through some bee-journal the receipt of the Chapman honey-plant for your *individual* use and experiments, and that it is being tested by you; also report in some journal, and to me, the result of your experiments.

One thing I ask as a favor to myself, and to all bee-keepers everywhere—Should you find that it does not thrive well, or prove successful in your particular locality, do not be hasty in condemning the plant as a failure, for not you alone are testing it; it is being experimented with, through a vast extent of territory, from Massachusetts to Nebraska, and the variation in soil and climate will probably exert a marked influence on its growth.

You can set the plants nearer if you wish, but you must consider that if your plants do well they will bloom three years or more. Set the plants in good soil, for the roots are old and they will develop. They will not bloom as early as mine will at home.

The Chapman honey-plant is a member of the great family to which the thistle belongs, and in some respects resembles the thistle. It has not, however, the features which make the thistle so obnoxious, for it does not send its seed broadcast on the wind, nor spread from the root, and is easily eradicated from the soil; but to save the necesity of overcoming the popular prejudice against any thing called "thistle," I think it expedient to avoid giving it that name, and therefore request you to refrain from referring to it as "thistle" in any report you make, or article you write concerning the plant. HIRAM CHAPMAN.

Versailles, N. Y.

BOOK-REVIEW DEPARTMENT.

EXPERIMENTS IN APICULTURE, BY NELSON W. MC LAIN.

A COPY of the above report has been sent us, and, as was to be expected, we are not disappointed as regards its contents. In it the student interested in the science of apiculture will find a field opened for investigation. The experiments therein contained are interesting, and some are quite conclusive on some of our old disputed questions. The whole is worthy of a reprint in GLEANINGS; but as our space is crowded I will try to give a birdseye view of it, accompanied with several extracts. First we will consider

ECONOMY IN THE PRODUCTION OF WAX.

At the National Convention at New Orleans, Mr. Paul L. Viallon, in a paper which he read, stated that, in his opinion, the bees did not consume 20 lbs. of honey to make 1 lb. of wax; that this estimate was too high. According to his experiments, the consumption of only 7 lbs. of honey was required to make 1 lb. of wax. Prof. McLain, however, verifies the old estimate. He says:

> If account be taken of the loss resulting from having the time and energies of the bees expended in wax-production instead of honey-production at a season of the year when there is most imperative need for uninterrupted and diligent activity in honey-gathering, and of the value of the honey consumed in producing wax, and of the labor required in preserving and preparing the wax for market, it will readily be seen that the production of a pound of wax costs the producer many times the current prices realized. About 20 pounds of honey are consumed in producing 1 pound of wax.

From the fact that McLain's estimate of the cost of wax is backed by former experimenters some years ago, it would seem that 20 lbs. of honey to 1 lb. of wax is very nearly correct.

WINTERING BEES.

After speaking of the different methods of wintering, and the conditions of success, the author believes that the lack of water to colonies in winter quarters is one very potent cause of dysentery. Here is what he says:

> Excessive thirst, and prolonged low temperature, cause what is called "roaring in the hive." Disquietude from any cause induces excessive consumption; dysentery follows; death usually results. I have frequently quieted roaring in the hive, and restored the bees to their normal condition of quietude, by supplying water.

To supply the bees with water, a moderately wet sponge is placed in a hole bored in a suitable block. The whole is placed over the cluster, under the blanket or cushion. The addition of a little salt is recommended as being a preventive to dysentery. The water, he says, should be given when the weather is suitable, and he thinks it will largely prevent the loss of valuable colonies which might otherwise be lost.

BEES VERSUS FRUIT.

For thoroughly testing whether bees could injure fruit, a bee-proof building was constructed expressly for the purpose. The sides of the building were so made that they could be opened, and wire screens complete the inclosure. A stove was placed inside, so as to maintain a high temperature, and also to bring about as nearly as possible an artificial drought. Fruit of various kinds, especially grapes of the different varieties, was obtained from numerous sources, and placed inside. Three hives of bees on empty combs were also placed inside—two of the swarms being hybrids and the other Italians. As to how the bees regarded the fruit, the author says:

> The bees were brought to the stages of hunger, thirst, and starvation. The house was kept locked, and we carried the key. Every inducement and opportunity was afforded the bees to satisfy their hunger and thirst by attacking the fruit exposed. They daily visited the fruit in great numbers, and labored diligently to improve the only remaining source of subsistence. They inspected and took what advantage they could of every opening at the stem or crack in the epidermis, or puncture made by insects which deposit their eggs in the skin of grapes. They regarded the epidermis of the peaches, pears, plums, and other fruits having thick covering, simply as subjects for inquiry and investigation, and not objects of attack. If the skin be broken or removed they will, in case of need, lap and suck the juices exposed. The same was also true of the grapes if the skin was broken by violence, or burst on account of the fruit becoming overripe; the bees lapped and sucked the juices from the exposed parts of grapes and stored it in the cells for food. They made no attempt to grasp the cuticle of grapes with their mandibles or with their claws. If the grapes were cut open or burst from overripeness, the bees would lap and suck the juice from the exposed segments of the grape until they came to the film separating the exposed and broken segments from the unbroken segments. Through and beyond the film separating the segments they appear to be unable to penetrate.

A test of this kind for 30 days, during which grapes of a thinner skin were tried, showed that the bees had no disposition to injure any of the varieties of fruit; and only when the grapes were rotten or broken open did they attempt to appropriate the juices. In one outdoor test, the grapes were dipped in honey, and the bees were allowed to get well started to robbing on them. The honey having all been licked off, the grapes were all left unharmed.

It is very gratifying indeed for us to know that these experiments have been made under the auspices of the United States, and that the results show that bees *do not injure fruit.* Whenever a controversy again comes up, we can with pleasure refer back to this report.

ARTIFICIAL FERTILIZATION OF QUEENS.

This has always seemed quite impracticable as well as impossible, and it is yet possible that the thing is not yet solved. Prof. McLain has struck upon a plan, however, which, to me at least, seems possible. In brief it is as follows:

After trying artificial fertilization in the cell upon imago queens without success, or, at any rate, with only partial success, he finally made experiments upon queens which had reached the age when they take their wedding-flight, or at the time when orgasm occurs. This, in most queens, is from 5 to 7 days from the time of hatching. His manner of accomplishing this result, we give in his own words:

> When orgasm takes place, the generative organs of the queen are highly excited and much distended. We confined a queenless colony in their hive, and gave them a queen-cell which had not been disturb-

ed while maturing, and allowed the queen to hatch. When the virgin queen was six days old, orgasm occurred; and on the evening of the seventh day we removed her from the hive and placed drops of the male sperm upon the open vulva as she was held back downward, by gently grasping the thorax between the thumb and forefinger. The instant the male sperm was pressed from the testes and seminal sack of the mature drone upon the excited and distended vulva, it was curious to observe the effect. The action of the abdomen and vulva resembled that of young birds while being fed. There was the reaching up after the seminal fluid, and an action of the parts resembling the opening of the mouth and swallowing food. As much seminal fluid as could be obtained, by the imperfect method employed, from three or four drones, was utilized and readily absorbed by the queen, after which her wing was clipped, and she was dropped on a frame covered with bees and returned to the hive, and the bees were liberated.

This queen, he states, after assuming the appearance of a fertilized queen, soon began to lay, and her eggs in due time produced well-developed workers. Observe, that the bees were confined prior to the queen's fertilization, and after which her wings were clipped. Of course, it does not seem possible that the queen could have been fertilized by natural means, and yet she *might* have been. The field is now opened; and if Prof. McLain shall again meet with the same results in future experiments, and his work be verified by others, we shall then conclude that *artificial fertilization is possible.* We await the results.

IMPORTANCE OF APICULTURE.

Under this head I clip the following:

> The estimated annual product ranges from $15,000,000 to $20,000,000, and the annual product of wax is about $1,000,000 in value. Not more than 8 or 10 per cent of those favorably situated for the cultivation of bees are engaged in the pursuit. If even one-half of those favorably situated were so engaged, the annual product would not fall below $75,000,000 or $80,000,000 in value.
>
> The United States imported 2,400,000,000 pounds of sugar, at a cost of $94,923,500 in the year 1884.

In conclusion, for fuller details than I have been able to give, I would refer you to the report of "The Experiments in Apiculture," as issued by the author, Nelson W. McLain, Aurora, Ill. After you have read carefully the report, I think you will agree with me that Prof. McLain deserves a vote of thanks from the bee keepers for the work he has done. E. R. ROOT.

HUMBUGS AND SWINDLES

PERTAINING TO BEE CULTURE.

I READ your article concerning D. Staples sending out dead blueberry-plants. I sent one dollar to him March 15 for two dozen plants; and as they did not arrive by April 26, I sent a card to him to send them on. May 1st, a small package of dead sprouts, no roots at all, and as dead as a door nail, came. He should be advertised far and near. It is worse than stealing, to my notion. FRED WIRT.

Keithsburg, Mercer Co., Illinois.

Friend W., we have placed to your credit the one dollar you have lost in this matter; and we will do the same with all the rest of our friends who have sent money to Delos Staples, and received nothing of any value in return. We hope other papers will take up this matter, and expose his business, before he can swindle many more through his advertisements.

HOW SHALL WE GET BEES OUT OF THE SECTIONS?

HOW ONE OF OUR FOLDING TENTS MAY BE UTILIZED FOR THE PURPOSE.

YOU ask me, in your foot-notes to my article, Apr. 15, page 298, "How does friend Vandervort get the bees out of the cases?" I frankly confess I don't know, and this has been a vexed question with me ever since I have kept bees. For the last two years I have smoked and shaken out all the bees that I could, and then piled the cases up across each other, and set the folding tent over them with a small hole cut in each end at the top, and the most of the bees will usually leave in a few hours. I wish that C. C. Miller, James Heddon, or some others of the leading bee-keepers, would tell us how they get the bees out of the boxes. Some colonies have the habit of uncapping the honey as soon as the hive is opened. How are we going to manage these, for such honey is unsalable at the best prices?

This has been a cold snug winter here, and bees have dwindled some this spring; but we are having fine weather now, and the bees are building up very fast. 10—GEO. A. WRIGHT, 95—80.

Glenwood, Susq. Co., Pa., Apr. 21, 1886.

ARTIFICIAL PASTURAGE.

THE GOODHUE PLAN (SEE PAGE 327).

I AM satisfied, after a six years' experience of the method of artificial pasturage which I spoke of on page 327, it will produce surer, greater, and more satisfactory results every way than all other methods of artificial pasturage combined; while for cheapness, simplicity, and ease of working, I do not see how any other method can compare with it. I do not mean, however, that it should supersede all other plans entirely, but I think it should be given far the foremost place. I bought 500 lbs. of alsike last week, and expect to get most of it sown within two miles of my apiary. The total expense of getting it sown will not exceed $10.00, and less than one day's time. Without my exertions, one-fourth of the above amount might perhaps be sown near me; and with very little care and trouble I expect to *quadruple* the quantity. Perhaps some of our experienced bee-keepers might like to make an estimate of the quantity of honey this extra 375 lbs. of alsike is likely to produce during the coming three years; thus they might make a calculation to try to find out how much it would cost to produce an equal quantity of the same quality of honey by any one or all of the other methods of artificial pasturage now known. I should like to see how such a balance-sheet would look.

I think if this plan were faithfully tried for a few years we should hear far less complaint about overstocking. GEO. O. GOODHUE.

Danville, Que., Canada, April 29, 1886.

I think you are on the right track, friend G.; and from reports we have had, and also from personal experience in our vicinity, I am inclined to think that the cultivation of alsike is the most practical undertaking that has opened to us, to improve our honey-flow. Neighbor H. has repeatedly had good yields of honey in his apiary where he had fields of alsike near, while the other apiary, five or six miles away, where no alsike was near, gave hardly any honey.

LETTER FROM SOUTH AMERICA.

CAN THE BEE-BUSINESS BE PURSUED PROFITABLY FROM THE SALE OF WAX ONLY?

THE honey-business is worth nothing here. You couldn't sell large quantities at 2 cts. per pound. My sole hope is the vinegar and the wax. Can modern bee culture be pursued to advantage by raising wax only? Beeswax is worth here 30 cts. per pound, and still more in candles. If an apiary can be maintained with profit for the wax principally, please give me, in your next issue, full particulars of the method best suited for this design. Do you think some honey mixed with the cow's beverage would improve milk or butter? Is there any book about the uses of honey? Can candy be obtained from honey in hot weather, by artificial process?

MIGUEL RIBEIRO LISBOA.

Barbacena, Brazil, April 8, 1886.

Here is something else in the same line, from one of our friends in Mexico:

As bee-keeping in Mexico is an affair conducted in a manner entirely without skill, *El Industrial Mexicana*, a monthly cyclopedia of which I am the editor, is now giving the first information on this subject. As we have neither use nor demand for honey, we are compelled to get all the profit on bee-keeping from the sale of wax, which ranges in price from 16 to 17 and 19 cts. per arroba (25 pounds). Wax has a very large demand in this country, and one could sell as much as he could get. Now, Mr. Root, does your A B C book give especial information for stimulating bees to build comb instead of gathering so much honey? You know folks don't eat honey in this country.

J. GARDIDA.

City of Mexico, April 15, 1886.

Dear friends, we are very glad indeed to get letters from so remote points, and we shall be very glad indeed to make GLEANINGS a medium for helping in the production of wax instead of honey, as far as it may be possible to do so. This matter has been discussed in our back volumes. The principal experiment we now think of is the one by friend Hasty, somewhere in our back numbers; also see A B C book, p. 288. Also see GLEANINGS for 1883, page 67.

While wax was worth from 35 to 40 c., and we we were obliged to import it from Europe in order to get enough to supply the demand for comb foundation, it was considerably talked of. The market price now, however, is only from 20 to 25 cts. Still, as the price of honey has declined in about the same ratio, it may be well to consider the production of wax in our apiaries, as well as the production of honey. One thing we may do with safety, in any event, and that is, take pains to save every particle of wax the bees produce, allowing not an ounce to go to waste.

We shall be very glad to get reports in the matter from any of our readers; but so far I believe experiments have not resulted very encouragingly. With a mild climate, however, and an uninterrupted flow of honey, no doubt the chance might be much greater for success. I have never heard the question discussed as to making cows eat honey. I suppose it is because it costs too much here. Cows are very fond of maple syrup, or sap, however, and no doubt it might augment the quantity and quality of milk and butter. Friend Newman of Chicago, Ill., has a little book called "Honey as Food and Medicine." We mail you a copy. The A B C book tells something about bees building comb. We have sent you a copy, and hope you will find it helpful.

CLOSING THE ENTRANCE OF HIVES DURING WINTER.

HOW TO KEEP A CELLAR COOL.

ALTHOUGH but a novice in bee culture, yet I have often wondered why apiarists did not recommend the closing of the entrances to the hives when putting them into winter quarters, so as to prevent their flying out. Last fall I put 11 colonies, carefully prepared, into my cellar, with the entrances open as directed. The cellar was well ventilated, and quite dark; yet the bees would come out by the hundreds, and, of course, perished. Now, I should like to know what evidence there is to show that a large proportion of those lost would not have lived to protect the young brood in the spring if they had been prevented from flying out. Two of the colonies died before March, and I fear that several of the others are quite weak, and that spring dwindling will follow.

Now, Bro. Root, I should like to ask what evil could result by keeping the entrances closed with wire screen, or something of that kind, at the same time being careful to keep the openings clear of dead bees, and giving them a good fly once in a while on fine days. The weather becoming very warm for several days, after the middle of April, the bees became uneasy; but having obtained some snow and ice during the winter I placed a pailful once, each warm day, in a tub on top a barrel in the cellar (17×30), and made the place totally dark, and the bees became as still as mice.

Last fall a neighbor of mine put 13 strong colonies, with lots of honey, into a warm cellar; but they were exposed at times to the light of the sun; and the result was, the bees came out by the thousands, and were chilled to death; and before the first of March, 9 out of the 13 were dead, leaving from 12 to 30 lbs. of honey per colony behind. Now, who will venture to say that, if the entrances had been closed, as suggested above, the bees would still have perished. I for one must acknowledge being very skeptical in the matter.

W. C. WHITE.

Hamilton, Ont., Can., April 26, 1886.

Friend W., the matter of closing the entrances in winter has been very fully discussed in our back volumes. Sometimes it succeeds very well, and at other times the bees crowd about the entrance, become excited, and may be smother the whole hive in their frantic efforts to get out. I believe it has generally been abandoned. We practiced it several winters; but instead of trying to confine the bees by fastening wire cloth over the entrance, we put wire cloth over the whole top of the hive. Those fastened in their hives wintered about as well as the others. We noticed very little difference.

WHAT KILLED THE BEES, ETC.?

LAWYERS FOR BEE-KEEPERS.

I WENT into winter quarters with three colonies, as I thought good and strong. One died, and, strange to say, it died with plenty of natural stores. I could not account for it. When I examined them in January there was but about a single handful of bees. These were on a center comb, in the middle of which was a small patch of brood about as large as the palm of my hand. They had plenty of pollen, as well as honey. We could not find any queen. What do you suppose caused them to "play out" in that style?

I started in the spring with two colonies. I did not let them swarm. We had a poor honey season in our neighborhood, but I sold about $9.00 worth of honey and wax, and ate about $1.00 worth. It was all comb honey. I was not at home, except at night, and consequently had to keep the bees in the house where I slept. We got along finely together.

A DOG EATING BROOD.

In GLEANINGS for Nov. 15, I. R. Good speaks of "eating queen-cells." This reminds me, that, summer before last, while I was transferring some bees for my aunt I laid a piece of brood out to one side, and when we went to look for it the dog had eaten it up. It was a good large piece of brood too, quite as large as my hand.

SWARMING BEES.

In the latter part of 1883, a lawyer of Burnet, through my influence, bought a swarm of bees; last summer his bees swarmed, while court was in session here. As he was expecting it he asked a gentleman in the court-room one day if he knew any thing about swarming bees. His friend said he did.

"Come," said the lawyer, "and go with me to dinner."

He went. The bees had settled in the top of a sapling.

"Now," said the guest, "you take an empty box and hold the open end up to receive the bees, while I shake them off."

My legal friend obeyed, while his guest procured a large stone, quite as much as he could handle well. He struck the sapling a tremendous blow.

The bees covered the lawyer, who dropped the hive and pursued his friend, whom, I need hardly say, had taken to his heels. Round and round they chased each other, through the orchard and over the garden. Of course, a string of bees followed as they went.

"I thought you told me you knew how to swarm bees," was the first question asked.

"I do; but I don't know much about hiving them," was the answer.

FIGURES AFTER THE NAMES.

Please tell me what those figures before and after the bee-keepers' names indicate. I thought at first it was to show how many colonies one had; but how can one determine, when figures are used both before and after names? C. W. HARDY.

Burnet, Texas.

Friend H., I do not see any thing strange about the way your bees died. The colony was so weak that their queen died, and then the rest, as a natural consequence, followed. The queen laid the eggs that produced the brood, before she stepped out. We generally suppose that a lawyer can do almost any thing if he sets about it; but it seems in the above case that the combined talent of *two* lawyers didn't manage that swarm of bees successfully.—Figures before a name mean so many years in the business; after the name, the first number means fall count, and the other spring count.

* * *

POLLEN FROM THE CACTUS.

WHAT IS THE DIFFERENCE BETWEEN A WASP AND A HORNET?

AFTER reading what Ernest said about bees working in rye meal, I went out into a pasture opposite our house where I saw them gathering pollen from the cactus flowers. I noticed one of them alight in a flower three inches across, containing enough pollen, I think, for half a dozen loads. When he came out of his bath he was yellow with pollen; and hanging to the edge of the flower, sometimes by one foot, with a quick motion of his other legs the pollen was scraped into the baskets, and with the middle legs neatly packed down, after which he flew away. On returning to the house I secured some pollen from an incoming bee, and found that it was quite sweet, while that in the cactus flower was tasteless. This confirmed the opinion which I have entertained for a long time, that, in packing the pollen in their baskets, they used honey to stick it together, and the honey is supplied from some secretive glands. While the pollen adheres readily to the bee, it did not adhere to my finger, which was even moist with perspiration. The cactus is rich in honey as well as pollen, but it can not be reached by bees. If honey were as plentiful in proportion, in this locality, as pollen, the yield would be immense. My bees brought in pollen last winter as late as December 15th, and commenced again on the 14th of February. There are but few periods when pollen is not abundant. In a week or two, cactus will be in full bloom.

About two weeks ago drones made their appearance in one colony, but were soon dispatched. The young drones were even torn from the cells and carried out.

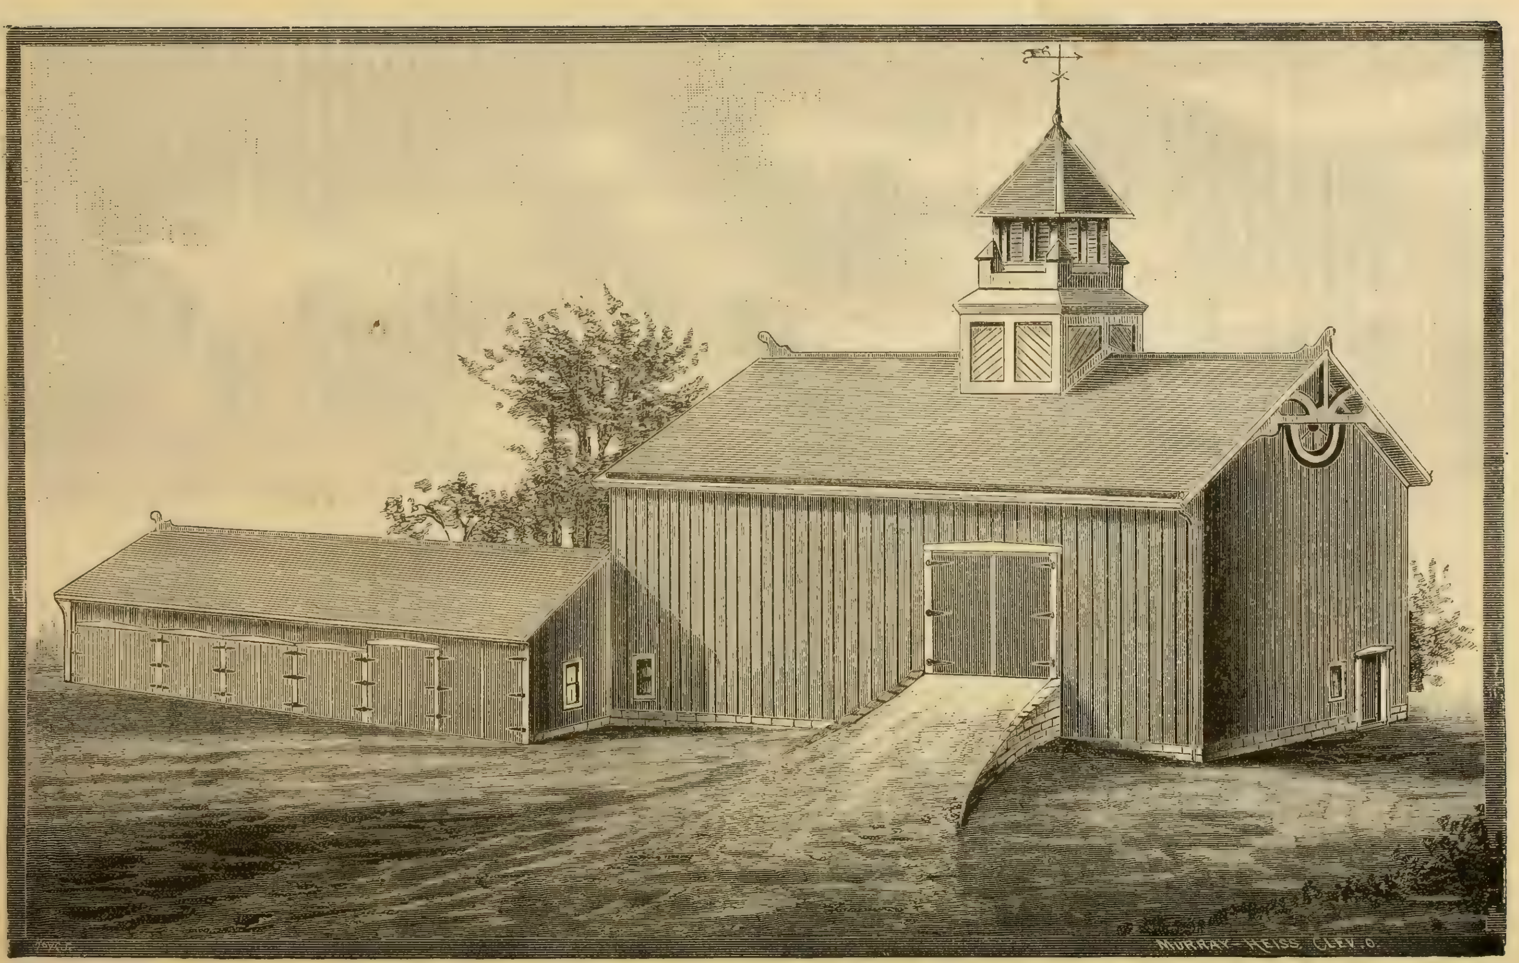
Why are robber bees nearly always black and slick? I mean those professional robbers.

What is the difference between a wasp and a hornet? Please describe the kind of nest that each of them builds. Can a wasp or hornet prolong the development of its young by withholding food?

I often see my bees come in so heavily laden that they have to stop on the alighting-board half a minute, and fan themselves, before they can enter the hive. T. F. MCCAMANT.

San Antonio, Texas, April 22, 1886.

Friend M., I guess you have hit the motions, in regard to handling the pollen, about right. I supposed the drones were turned out because of a dearth of honey. The professional robbers become black and slick by squeezing out and in small holes. Sometimes they get their fur pulled off by the sentinels of the hive grabbing them. — Your questions in regard to wasps and hornets come rather under the head of entomology, and I feel sure that Prof. Cook will tell us about them, especially the matter of prolonging the development of the young.



MURRAY-HEISS CLEV. O.

T. B. TERRY'S MODEL BARN AND TOOL-HOUSE, HUDSON, OHIO.

EXTRACT FROM TERRY'S NEW BOOK.

SOMETHING ABOUT HAY; THE DIFFERENCE BETWEEN HAY MADE ON DRAINED AND UNDRAINED LAND, AND SOME KINDRED MATTERS.

WE are so much pleased with the new book mentioned above, that we have decided to give our readers a single chapter as a sample, and in connection with it we submit a picture of Terry's barn and tool-house, shown on the opposite page. The tool-house was illustrated and described last fall, on page 720, GLEANINGS for Oct. 15. The description of the barn is almost too lengthy for our columns; but it is so intimately connected with the subject-matter of the book that the book is built up in and around the barn, as it were. The following chapter, you will notice, comes in just abreast of the haying season:

WHAT KIND OF HAY?—DRIED GRASS, RAISED ON FERTILE DRAINED LAND.

If the reader has decided to keep his stock in a warm comfortable stable, and to feed and water them properly, the next question which naturally arises is, What shall I feed them? We will discuss this question rather fully in this and following chapters, and perhaps get a little off from our text now and then, as it is a very important subject.

On many farms the answer to this question may be such as to give the owner an opportunity for a grand success or a bare living. These are pretty strong words, but they shall be made good before these chapters are finished, by facts that no one can gainsay.

First, in regard to the hay fed, let it be early-cut or dried grass, and a good share of it clover, if clover can be made to grow on your soil. To this, my friend Mr. D. E. Fenn, of Tallmadge, at our farmers' institute, held in Cuyahoga Falls, added, "Let the grass be raised on well-drained land." He thought that tile-draining would pay for grass and clover, as the hay is of better quality. There is no doubt but that he is right. The hay should be raised on fertile, well-drained land. Hay isn't hay, any more than butter is butter. I saw a merchant buying butter of a farmer for 12 cts. per lb., the other day; and if any one, I think the merchant got cheated. I bought a crock of my neighbor, and paid 28 cts. per lb., and it was worth it. Now, I have seen hay grown on rich drained land that would yield four tons or more, in two or three cuttings, during the season, and hay grown on land so poor, and filled with stagnant water, that it would not think of making more than one crop in a season, and that, perhaps, half a ton to the acre, or three-fourths; and there was as much difference in the feeding value of those two lots of hay as in the value of the two lots of butter spoken of. In the case of the butter, possibly analysis would not show much difference in the component parts of the two sorts; but our senses of taste and smell are not governed by analysis. We like a fine flavor and aroma; so do our animals. I have never known of any analysis of the two kinds of hay mentioned above; but from experience in feeding I should think there must be a decided difference in their component parts; at any rate, the cattle know which is most to their liking.

A friend was once rather making fun of my rank, coarse hay, grown on rich drained land. He said the cattle would take his finer hay, grown on land that produced only about a third as much per acre, first, every time; that all stock liked such hay better; that mine was too coarse and woody. After some dispute we agreed to leave the matter to be decided by a lot of cattle I was feeding in the stable. We put samples of his hay and mine along in the manger, so the animals could take their choice, and, much to my friend's disgust, they took my "woody, coarse" hay every time. No need of analysis to tell them which was the better. It doesn't follow, of course, necessarily, that they would not gain as much flesh on a ton of my friend's hay as on a ton of mine, although it was not as well relished; but from other experiences I feel sure they would not. The matter of relish alone goes a good way. When hay is, as one farmer expressed it to me, "medicine" to one's cows, the best results can not be obtained.

When I first bought my farm, which had been rented and abused till no one wanted to rent it at any price, we mowed over a good many acres to get a few tons of hay; and although it was cut reasonably early, the quality was so poor it would hardly keep the breath of life in the stock during the winter. Grain was bought and fed with it, and thus we managed to get along. Since that time, cattle have been sold for beef in the spring—not very fat, of course, but good fair beef, that had not had a pound of grain during the winter. This has been done as an experiment, to see what could be done with choice hay alone; but it is not, of course, the wisest way. Cows have been milked twice a day all winter, giving a good mess of milk, on dried grass alone. Horses have drawn heavy loads of potatoes and wheat to Akron to market, some twelve miles, fed on hay alone, week after week and month after month, some years, and kept in fair order. These horses would have given out in one week, if fed on the hay we first raised, before the wet land was tile-drained, and tillage with a little manure and clover had made our land fertile. So they would have given out in a short time if the hay had not been cut early, when at its best, and if a part of it had not been clover. I am not advising any one to keep his horses on hay alone, but am merely using my success in this line to illustrate what can be done with prime hay. My work-horses are kept this way because I can keep them healthy, and ready for business, on such feed, cheaper than on any other. One needs, however, the right kind of horses — not of the slim race-horse breeds — and they need the right kind of driving.

When I began farming, hardly any one in this vicinity thought of cutting any hay until along about the last of July, and many were still later. I was new at the business, but common sense told me to cut the grass when it was green, and relished by stock, and not let it stand until it was so ripe as to be no better than straw. Farmers used to say to me, "Why, your hay will all dry away cutting it so green, and then you lose a good deal of weight by its not being more than two-thirds grown." They forgot that the second crop came right on as soon as I cut the first off, and made as much growth in the same time, perhaps, as the first would if I had left it standing. If it did dry away a little more, what was left was extra choice, and more than made up in quality what it lacked in quantity. About the first of August the second crop was cut — about the time others were securing their first one; and some years three crops were cut, the last one about the first of October. Some laughing was doubtless done at the town-bred book-farmer; but when he began to increase his stock until, instead of nine cows, forty to sixty were in the barn in winter, it was evident that something was the matter. We do not claim any credit; but numerous mowing-machines are now running as soon, or sooner, than ours. Our best farmers who raise wheat strive to get their haying all done before the time of wheat-harvest. But in traveling over the country, one sees large quantities of grass standing for weeks after it ought to have been cut. Then the farmer feeds grain—bought, or of his own raising—with it, to make it young again, or to make it as good as it might have been alone without grain, if it had been cut at the right time, and properly cured. Probably its being more difficult to cure is one reason why all do not cut their grass earlier. It is some more trouble to cure early-cut hay. Usually, the better a thing is, the more it costs. The easiest way is rarely the best way. It is easier to shake apples from the tree than to pick them; but it is hardly the best way. It is easier—takes less labor—to stack our hay, and feed the stock around the stack; but few farmers, however, can now be found in this part of the country who will advocate the plan. It is easier to let the grass stand until about ripe, and then cut it and follow right up with the rake and get it right in. There is no fussing or bother. One can keep the men right at hard work all the time, and shove the haying right along. I will admit all this; but when your cows look pinched and unthrifty next spring; when their excrement is almost as hard and dry as a stone; and when the first warm days come along, and you have to begin "shoveling the corn meal into them," and every now and then have to call in the neighbors to help lift one up; when you have got a few hides on the fence, and the milk of your dairy will hardly pay the feed-bill; then, if you are not prejudiced, you ought to begin to "see where you missed it;" to see that the easiest way is not always the best. What was the trouble? Why, you had, for one thing, let your grass stand until it had lost one-half of its value; then you expected your cows to return you full value on it, but you couldn't cheat nature. The effect follows the cause; and for every dollar you saved in trouble at haying time, you may have lost five. This you have a perfect right to do, if you can stand such business; but have you any right to half starve those poor cows? Think of the suffering they endured, which you could have prevented if you had cut that grass at the right time; and then you would like, would you not, to see those cows all on their feet, strong and healthy, the hides all animated once more, their manure thin and healthy, as in summer time, and a good flow of milk coming from them without feeding them much grain? Wouldn't your prospect for milk this summer be much better than now? Will you think of this, and hire an extra hand, and begin your haying early another year, and get it all secured, if possible, before wheat-harvest? Your cows will thank you, and you will begin to have more faith in the stories you hear of dairymen who make $60.00 or $70.00 from a cow in a single season.

Another reason why hay is often left to stand too long is, that the farmer has too many irons in the fire, or too much to do. His farming is not properly arranged so as to prevent clashing. The farmer who undertakes too much often loses by it. Some crop must suffer. If the hay can be secured before wheat-harvest, well and good; you can raise wheat and not have any clashing. If a part of it has to stand over for two weeks while you are cutting and getting in your wheat, you may lose as much on the hay as you make on the wheat.

MY REPORT FOR 1885.

IS THIS A GOOD LOCALITY FOR HONEY? WHAT SIZE OF SECTION IS BEST?

THE last season here was again short; at least, we call it short. Doolittle would not think four or five weeks of good honey-flow very short, estimated by his experience of a good yield. The white-clover harvest lasted about five weeks, but it always takes bees here a week to get started, so they stored all their surplus, I might say, in four weeks. In that time I got 40 to 50 lbs. from my strongest colonies, together with a swarm. After July 4th nothing was done, except that a few managed to fill out a few sections already nearly full. This is nothing to compare with Mr. Doolittle's reports for 1885; yet, so far as my experience goes, bees gathered honey as fast during June as they ever do. It was evidently drought that cut short the white-clover harvest. Later in the season there was a great deal of heart's-ease, and the fields were yellow with Spanish needles; yet I did not secure 20 lbs. of honey from these flowers; and what I did get was stored in empty combs. They stored in the brood-chamber enough to keep 60 stands until the last of April, I think, but I shall have to feed some to carry them till clover season, unless fruit-bloom yields a great deal more than it has of late years. This later season was not too dry; the blossoms ought to have yielded honey. Why they did not, no one here seems able to tell.

THE SUMMING-UP.

I started into summer with 45 stands, which would have made about 30 good ones. I increased to 75 by natural and artificial swarming and uniting, besides a few swarms I lost. I obtained 900 lbs. of comb honey; one-tenth of it, perhaps, not very well filled out, and 400 lbs. of extracted, all from white clover.

Those 75 colonies I doubled down to 60 for winter. I think I shall average 15 cents per lb. for the comb honey, and a fraction over 10 cents for the extracted. I market all in Springfield, and the country and villages around. This result of 25 lbs. to the stand is rather small. The showing is better when I consider that nearly all was obtained from about 30 colonies, a number of which were not able to go into surplus boxes until the middle of June, bringing the average up to 40 lbs. But even that is no very great affair compared with the reports of our best bee-keepers. I am, however, better satisfied than ever before. I feel that I have worked to better advantage, and succeeded better than I have yet before done. I have certainly done a great deal better than any one else around here. The general verdict of my neighbors is, that bees do not pay. I should think not, the way they manage. Some with several colonies have not taken off 5 lbs. of surplus, and none of them very much. I suppose two-thirds of the bees will starve out as they did last year. I had just carried a case of honey into a store last August, when neighbor Ike came in. He looked at my honey, in nice Simplicity boxes, I tell you.

"Why, George, how is it that you can get so much honey when none of the rest of us can get any?"

"Simply because I take care of my bees—pay attention to them—put my time to them. To make any thing from bees you have to cultivate them the same as you would a crop of corn."

In June, 1883, an old gentleman about ten miles from here came to see how I fixed to raise section honey. He had then 35 stands, and he closed the year with 80.

"I do not do any thing with my bees," said he, "but hive them and take off the honey; but they always do very well."

A few weeks ago I saw him, when he told me he had gone from 100 down to 16, and the moth were taking them. He does not think "they do very well" now. I could tell several more stories of the same kind. When I compare these reports with many in GLEANINGS, I am led to inquire,

IS THIS A GOOD REGION FOR BEE CULTURE?

Does white clover yield more copiously in other localities than in this? Does the clover season last longer in other places? Here—Central Illinois—there is no basswood. White clover seems to be the only crop that can be depended upon at all. Heart's-ease and Spanish needle yield well sometimes, but they have failed the last three years, and fruit-blossom never has yielded much for me. In 1882 and '3 there was considerable honey raised; and if I had known as much then as I know now I could have produced 60, perhaps 75 lbs., per colony. But they were regarded as exceptionally good seasons here. Is this a comparatively good honey region, or is it even fair?

WHAT SIZE OF PACKAGE SHALL WE USE?

I can not agree with friends Root and Hutchinson, that a Simplicity section 1½ or 1⅝ inches wide is the coming box. The narrowest I have used is 1¾, and I am not going to order any more, I think. Why? Because they do not suit my customers. In Springfield a box that holds about a full pound goes very well. I have sold honey there in the old 1½-lb. and 2-lb. boxes, and the merchant who has sold as much for me as all others, there and elsewhere, told me once that he did not see but the larger packages sold as well as the smaller. This fall I took him a case of 1¾ boxes, and his customers did not like them. Nearer home I find that the largest boxes actually give the best satisfaction. That fact, and the fact that they are continually complaining about the price, makes me think more than ever what I said over a year ago, that it is not best to throw away all our old bulk boxes; for I certainly think that honey can be produced with less cost in that form. Certainly it will pay me to use several hundred large sections; and if it will pay me, why not others? Also, if they do not like honey in smaller than pound lumps in Springfield, I do not see why they should not dislike them elsewhere.

GEO. F. ROBBINS, 45—75 60.

Mechanicsburg, Ill., Jan., 1886.

REST FOR THE OVERWORKED.

MRS. CHADDOCK TELLS US HOW TO OBTAIN REST, AND STILL BE BUSY.

DOCTORS disagree, so do friendly advisers. I am fully persuaded that, if I had followed one-half the advice that has been given me, I should have been *non est* long ago. Now, they seem to have settled down on *rest* or *stir*. About half of them advise rest; the others say, "Stir out, stir out, or you will die."

I was in a large water-cure establishment once for a few weeks, and I then learned that to rich people the advice was daily given, "Rest is what you need, my good woman; complete rest; your mind is too active for your body, and if you do not rest you will land in the insane asylum." To the poor folks the same doctor said, "Stir out, stir out, young man; you don't want to go droning around here for ever. Use your will power—exert your thinking faculties, and get well."

One day the doctor lectured on "Rest." He said, "You want to lie down and rest, just as a horse or cow does when sick. Nobody has to tell a sick cow, 'You are better now, and I think you had better get up and go to eating grass.' No, sir; a cow just lies there till she gets well, then she knows it, and gets up and goes to eating. And don't keep all the time thinking about the money that it takes to keep you here; you had better spend every dollar that you have, and be cured, than live as you are living now."

It was a good lecture, and was applauded to the echo. Now, in the room next to ours was a poor young man who had stayed at the cure till he had spent all his substance, and yet was not healed, and the doctor walked straight from his lecture, with *rest, rest, complete rest,* still warm on his lips, and said to the poor young man, "Why, man alive, why do you lie here? Why don't you stir out? Stir out, I tell you. You have a thinking mind, do you not? Well, use your will power; force yourself to get up and out; take interest in something; you will die if you don't."

That convinced me that rich people ought to rest, and poor ones stir out. For my part I like the *stirring out*. I'd rather drive a mule team than play the piano. I can do it better, and there is vastly more fun in it; but part of the time I am not able to sit up, then I rest. As to Mr. Root's *resting* by digging the ground half an hour, that *was* rest.

Rest, according to my notion, is any thing that eases the strain on the nerves or muscles, or whatever is tired; and work that can be left at any minute whenever a fellow's back begins to ache is just the same as no work at all; it doesn't tire anybody. Now, if Mr. Root were baking a dozen pies, eight loaves of bread, and getting dinner for workhands, and waiting on a sick man all at the same time, and could not leave any of it till the dinner was over, I do not think it would be much of a rest. I like to dig in the ground for about ten minutes, then I want to change work with somebody. Sometimes I think that the pressure—the responsibility—the feeling that a thing *must be done*, is harder than the work.

As to going South, I had numerous invitations, but none from Florida, where I wanted to go. I had *warm* invitations from five States; and if I had had the dollars I should have traveled all around among the folks. As it was, I stayed at home and wrote love-stories; and the only geese that I picked were the editors who bought them of me. But I must go somewhere or see somebody pretty soon, for I have used up all the people I know—married them off and *deaded* them, and I now sigh for new characters. I do not think it is hard work that makes farmers' wives crazy, but it is the monotony—the staying at home for seven weeks, and never seeing any one but one's own family.

Vermont, Ill. MAHALA B. CHADDOCK.

PROF. COOK'S EXPERIENCE WITH MAPLE SYRUP, ETC.

A SIMPLE PLAN OF RESTORING MUSTY SYRUP.

FRIEND ROOT:—We thought we were the sweetest and most stuck-up people of the country at our house, as we have honey to sell and to eat, to give away and to keep. More than that, maple syrup from six hundred trees has helped to sweeten our food if not our tempers. Our relish for these incomparable sweets has made us glad that you at the "Home of the Honey-Bees" were equally sweet and equally "stuck up." In handling our syrup this spring we have discovered a fact of considerable practical and scientific interest. Through an accident, 5 gallons of syrup were put into a musty can. Syrup, like cream and butter, is very quick to receive taint from surrounding impurities, and so, as we might expect, this syrup was apparently ruined. I first boiled the syrup, and found the musty taste still pronounced and offensive. I then reduced a little of the syrup to sugar, and found it and the must still companions. After that I added equal quantities of syrup and water, and boiled for some hours till all was again reduced to the consistency of prime syrup, 11 lbs. to the gallon, when, to my joy, I found that the syrup was as fine as any ever eaten. I presume the same result would have been attained had no water been added, and the syrup repeatedly heated to the boiling-point and cooled off.

This is quite in line with the admirable experiments of Tyndall. He found that many fungi could be killed in his flasks, and the contents rendered sterile, by prolonged boiling and speedy sealing while hot, while boiling for a brief period did not render the liquids sterile. The theory is, that the liquids contain the fungi and the germs. The fungi are killed by brief boiling, which does not kill the germs. Prolonged boiling or repeated boiling either kills the germs or else develops them, after which a brief boiling destroys them.

This fact has much of practical value to suggest. If syrup is tainted in a sugar-bush by putting it in a musty vessel, it can be put in the front of the evaporator with sap, and again reduced, when all taint will have been destroyed. If any person has musty syrup, honey, or fruit, we note how the must can be destroyed. I have already suggested this treatment to two or three who have turned it to practical account.

Is it generally known that maple syrup will retain all its perfection of flavor, if canned and sealed while hot? We have had delicious syrup on our cakes all winter, and just as fine as when new. It is claimed by some of the Ohio sugar-makers, that, if vessels are filled full of the syrup when fresh, and then sealed tight, the syrup will keep as well as if canned hot. We are trying that with a little this year, and will report a year hence.

A. J. COOK.

Agricultural College, Mich., Apr. 21, 1886.

Why, friend C., is it really possible that you have a 600-tree sugar-camp? I would give almost any thing to see you out in the sugar-camp, directing sugar-making. We have had experience several times with musty syrup, and we never found out any way to remedy it better than scalding. But we have noticed this: That sometimes the scalding helped the matter, and then again it didn't; and you have probably given us the key to the different results at different times. I have repeatedly been told that adding water to maple syrup, and then boiling it out, always darkens the color. Do you not find this so? Here is something further from a friend near us, in regard to the maple-sugar industry:

WANTED, A BOOK ON MAPLE-SUGAR MAKING.

In making sugar this spring I have met with a number of important points on which I needed information, but could not get it. There are hundreds of maples about here that might be tapped with profit, if people could find out how to make a good article cheaply. Have you ever thought of a "Maple-sugar book," on the plan of the "Potato-book," the "Carp-book," etc.? In my opinion, such a book should not be written by an evaporator man—we can not afford to lay out $75 or $100 for a boiling-apparatus, and then sell syrup for 70 cts. or less per gallon. A $10 evaporator, a good arch, and proper information on how to manage the sap, the boiling, the canning—in fact, every thing, would prove valuable, I think.

As the primitive forest gradually disappears hereabouts, its place is taken by maples—some farms already having but few trees other than the maple. And there are not a few farms in this immediate vicinity that could tap from 500 to 1000 trees—a number that not many years ago seemed enormous.

If you conclude to do any thing in this line, I will try to do my share toward making the book a success by furnishing a list of questions that might, perhaps, be of some use to the writer or compiler.

ANTON LEISTER.

Brunswick, Medina Co., Ohio.

And now, friend Cook, can't you write this book, or get somebody to do it? I might add, that the finest syrup furnished us this season was not made with the evaporator at all, but simply with a common pan, boiling all the sap that ran each day, were it much or little, and keeping the utensils bright and clean, no matter how much trouble it might take to do it.

STRENGTHENING WEAK COLONIES.

DOOLITTLE'S PLAN OF DOING IT.

When spring arrives, most bee-keepers find that they have more or less weak colonies, even when their bees as a rule winter well; while now and then a spring finds some of us with a loss of nearly the whole apiary, and the few colonies remaining are mostly weak, or perhaps we have a part of the few weak, and a part strong. If many weak colonies are on our hands, and we are not anxious to augment our numbers, probably the best way would be to unite them till all are in comparatively good condition. But it more often happens that, when we have many weak colonies, we are the most anxious to save them all if possible, for we get many weak colonies only after a heavy loss during winter, in which case we are desirous to increase all we can, so as to utilize our empty combs before the moths destroy them.

Many ways have been devised to give strength to these weak colonies so as to keep them along till settled warm weather comes, so that they could build up; but most of them have proven failures when put in practice. The most general plan is that of giving hatching brood from the strong colonies to them; but as a rule this results in a loss of a part if not all of the brood; for the amount given must generally of necessity be more than the weak colony can cover and keep warm, while the young bees so hatched seem to lack the necessary vitality among so few old ones to keep the warmth up during cold nights; hence it often happens that all perish together.

If brood is given it is better to adopt the plan the editor did several years ago, which was to take a cake or biscuit cutter and cut out a small portion of a frame of brood, and all of that just gnawing through the cells, and insert this in the weak hive in the comb, which the few bees cover. However, this does not always work, as the editor well knows; besides, it mutilates the combs so as to spoil their beauty; and when wired frames are used it is out of the question altogether.

Well, after all my trials, I have at last struck on a plan which has so far worked to perfection, and by it I am able to put a weak colony right "on its feet" without materially injuring the strong ones. The plan is this: Take the wire-cloth box I have before described in Gleanings. Perhaps I had better describe it again here, so that the new subscribers can make one. Make a box of any size to suit you (I use one holding about six quarts), and cover the two sides with wire cloth. Through the top, bore a hole to admit the small end of a large funnel, such as is used by those who sell bees by the pound, and make a slide to cover this hole after the funnel is removed Now proceed to your strongest colony (if you have no such, one should be bought, if possible, as it will pay largely on the investment), and look it over till you find the queen. Put the frame she is on aside from the others, so as to make it impossible to get her in your box, when you will select a frame well covered with bees (or two partly covered). Now drum lightly on this frame so as to cause the bees to fill themselves with honey, and set it down by the hive. While the bees are filling themselves, put back the frame having the queen on, and adjust the hive, except leaving a space for the frame which the bees are on. As soon as they are well filled, adjust the funnel in the box, when they are to be shaken down through the funnel, and the box closed with the slide. After putting the frame back in the hive, and closing it, the box of bees is to be carried to a warm room and a blanket thrown over the box to keep it dark, when it is to stand three or four hours. During this time the bees will realize their queenless condition, and set up a great buzzing, telling plainly of their loss. Now go to the weak colony you wish to strengthen, and get their queen, which is to be put in with the bees in the box. To do this, set the box down suddenly so that all the bees will go to the bottom; then quickly draw the slide and drop in the queen, closing it again. Cover up again and leave until about sunset, or three or four hours more, when the bees will be found clustered compactly like a swarm. Now go to the colony from which you got the bees, and get a frame of hatching brood, without bees, and put it in the hive containing the weak colony, when you will at once hive the bees from the box on it. If the evening is at all cool I shake the bees from the box right on top of the frames so that none shall get chilled. I think all will see the "why" of the plan, without my explaining further.

G. M. Doolittle.

Borodino, N. Y., April, 1886.

Friend D., your plan will work all right, without any question; but you will excuse me for suggesting that there is too much machinery about it to suit *our* work. If I wanted to strengthen a colony during apple-bloom, or at any time when the bees are working fairly, I would just lift the frame—brood, bees, and all—out of any hive that could spare it, during the middle of the day, when most of the bees are in the fields, and set it in the hive that needs strengthening. I would be careful that the frame did not contain very much unsealed brood, however. As most of the flying bees are in the fields, the bees covering the combs in the middle of the day will be, as a rule, young ones; and with us, such a frame of bees will not quarrel nor be quarreled with, one time in ten. Just set them quietly between the combs of the weak hive, and let them get acquainted their leisure. If they do quarrel, a brisk at smoking will generally make them peaceable with each other.

MOSQUITO-BAR VEILS VERSUS THE GLASS FRONT.

REASONS FOR PREFERRING THE LATTER.

Some seem to think the objections to glass fronts very "obvious." Perhaps the glass fronts they have experimented with indeed bear their "obviousness" upon the *face* of them; but when any one claims that glass can not be so adapted to and inserted in veils as to render objections "few and far between," we are prepared to come forward and bear testimony to either his culpable ignorance or desire to misrepresent. We desire to present the claims that the glass front should have upon the favor of the progressive bee-keepers of our age.

Just here let me remark, that the bee keeper who is so reckless of the powers of vision that God has given him as to *strain* his eyes peering through a *no-glass* veil, deserves the punishment so surely to be meted out to him. What did friend A. H. K. Blood, of Quincy, Mass., mean when he wrote us it would have been worth thousands to him had he never seen a bee, rather than injure his eyesight as he had by using a veil without glass?

OBJECTION NO. 1.—"GLASS WILL BREAK TOO EASILY."

Then discard it from your windows and honey-packages. This liability depends upon the kind of glass, its manner of insertion, and the carelessness of the wearer. Some of our friends, little girls among them, have worn the same glass two seasons through. If an accident should break it, it is but the work of a moment to insert another. Better a little trouble this way and have the satisfaction of *unobstructed* vision.

OBJECTION NO. 2.—"TOO MUCH TROUBLE TO KEEP THE GLASS CLEAN."

My friends, if you expect to enjoy the good things of this life and shy around *trouble*, you will be "weighed in the balance and found wanting;" but let us suffer the "accumulated dirt of ages" to gather upon the glass, and we are not peering through so much *misery* as when trying to exercise a clear vision through a *mosquito-bar*, or Brussels net, if you please.

However, no need of "seeing through a glass darkly," when it is as easily kept clean as your spectacles.

OBJECTION NO. 3.—"MADE OBSCURE BY THE DAMPNESS OF THE BREATH."

This is *not so*, even in cool weather, when a five-inch hat-brim is used; but allowing it for argument's sake, how easy and convenient it is to take up a fold of the veil and rub off dampness! Should this, for two or three months in the North, cause us to lay aside, for the remainder of the season, this "blessing to bee-keepers," as J. B. Mason, of Mechanic Falls, Me., terms the glass veil?

OBJECTION NO. 4.

In this you say, "Beginners can't use them; for if a bee should get inside, the novice would ruin the veil knocking him out." What a compliment to beginners!

OBJECTION NO. 5.—"GLASS, BEING SO HEAVY, JOSTLES ABOUT SO AS TO BOTHER ONE."

We guarantee our contrivance not to "jostle;" veil complete, glass 4×6 in., weighs 2¾ oz.

We unhesitatingly affirm, that a practical glass veil is a nearer approach to a God-send to bee-keepers (and all should use veils when so comfortable under them) than all your pollen theories, hibernating theories, non-separator appliances, two-story brood-fixin's, etc. Why? Because thereby are preserved those precious organs of the body, the eyes.

Now, dear *mine fraternally*, in conclusion, let me say that, if you want to buy a veil from us, all right; but our improvements are not patented, nor will they be, contrary to the wish of our friends; and by sending to us we will either tell you where you can get the material we use, or furnish it to you at a slight advance on cost, and you make your own veil; but under no circumstances use window glass, or you will be forever disgusted with the idea.

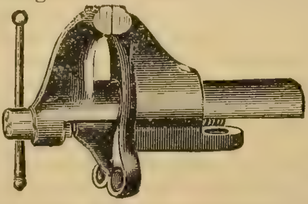
St. Albans, W. Va. J. C. CAPEHART.

Thanks, friend C.; but I don't quite see how you answer all the objections which you quote. Discarding glass from windows and shipping-cases because it will break when used in bee-veils doesn't necessarily follow. There is no possible substitute for glass in windows; as for shipping-cases, the very fact that the glass will break is a security against damage to the honey which it incloses, when handled by expressmen. Again, at the heading of the article you put "mosquito-bar veil versus the glass front." Against the former you seem to direct your arguments, and I think we shall pretty much agree with you there; but when you include a veil made of grenadine and Brussels netting, then I can't quite agree. I have used a veil of this kind six or seven different seasons in the apiary. I never had any difficulty in seeing, and do not know of any one who has injured his eyes by their use—I mean a veil with a front of a fine grade of *silk* Brussels netting. I have used several glass-front veils, and they all became more or less covered with steam from the breath, and half the time the glass *would* get out of place, so that one eye peered through the glass and the other through the mosquito-bar, making me feel vexed and cross-eyed. Although the glass may be a trifle clearer than the Brussels netting, yet as the latter never becomes greasy or covered with steam, in the long run the glass will be no easier on the eye. Lastly, the glass veil can not be carried in the pocket handily, and I always like to have a veil tucked away like a pocket-handkerchief for emergency, even if I do not use them now to any great extent. Nature's substitute, a full beard, does very nicely, besides catching the little rascal of a bee where his annoyance can speedily be put to an end. ERNEST.

HANDY TOOL FOR A SMALL AMOUNT OF MONEY.

A BENCH-VISE FOR ONLY 15 CENTS.

GREAT improvements have been made, not only in the *construction* of bench-vises, but also in the *prices*. A few years ago, no sort of a vise could be bought for less than a dollar or two. Finally some enterprising hardware men got one up that could be sold for 75 cts., and it had a large sale; and a little later a 50-cent vise was put on the market, and then one for 20 cts., which we advertised about a year ago. And now we take pleasure in showing you a very handy little vise for the almost insignificant sum of 15 cts. It is true, the machine is small, the jaws being only one inch wide, and the entire vise 3 inches long; but yet it is extremely handy for a great variety of work, just because it is small. The workmanship is surprising for so small a price. Prices are as follows:



OUR 15-CENT BENCH-VISE.

One, 15 cts.; 10, $1.40; 100, $13.50. If wanted by mail, add 6 cts. each for postage.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from April 15.

CHAPTER XV.

A PLANT-GARDEN.

Whatsoever he doeth shall prosper.—PSALM 1:3.

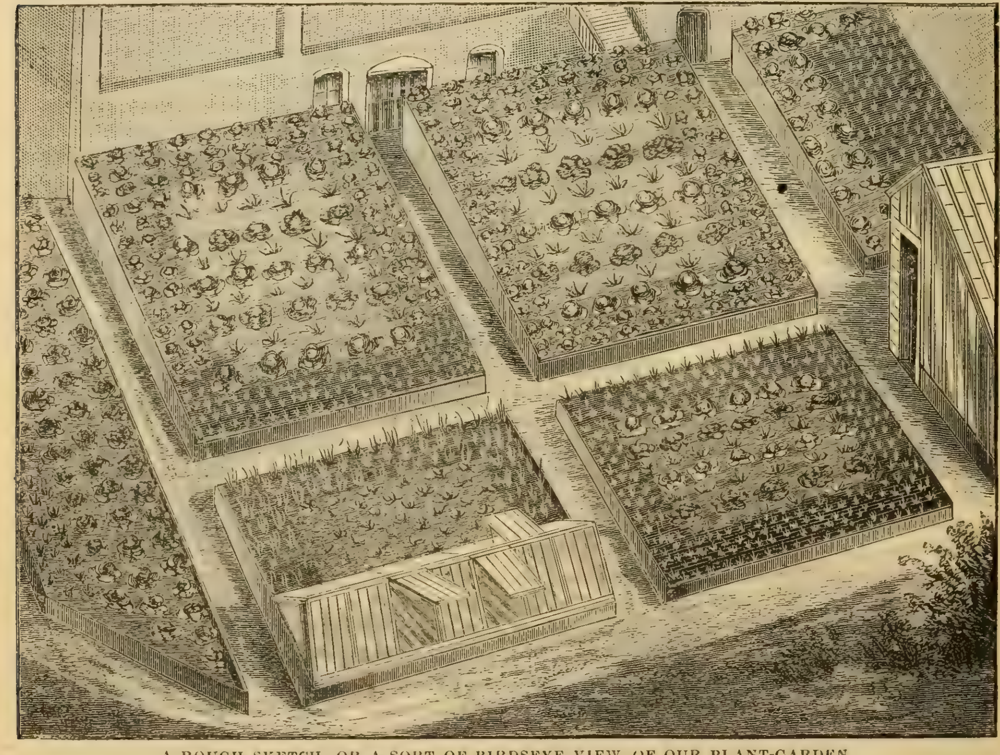
That is a pretty broad promise, dear friends, is it not? I do not know that the Psalmist meant to say that we should never have any bad luck, nor make any failures; but he meant that the man who is studying God's law day and night, and who delights to obey that law, would, as a rule, meet with success and prosperity. It is in the same line with the text that says, "All things work together for good to them that love God." Now, then, if I should tell you that your operations in gardening and poultry-raising would all prosper if you follow my teachings, it would be a pretty strong statement. Well, I do not intend to make such a statement; but I do mean to emphasize the promises in the Bible, each and all of them; and if, while your work is carried on, you are lifting your heart continually in love and praise to God, and working diligently meanwhile, you will surely meet with prosperity. You may have sickness and death, and tornadoes and whirlwinds, but there will be enough besides these to give you a thankful heart through all life's duties. Love is the mainspring of success in any thing. If you want to see plants grow, you must love them in the truest sense of the word; and if you want to see poultry do its level best, you must love the poultry, and love God through them, because they are his creation and his gifts.

It is now May, and we must move out of the greenhouse, out of the cold frames, and, in most localities, set aside the sash and other means of protection from the frost, and move out into the open field. Hand-work must, in a great measure, be laid aside for the cheaper and more economical labor of horses. But before stepping at once out into the open fields covering acres, we want to consider a sort of intermediate plan of gardening, as it were. This garden is to be an open field, only it is to be worked by hand, horses seldom if ever going into it at all, the ground being worked over by the use of the spade or spading-fork. Now, spading ground is very expensive compared with turning it over with a plow, and therefore we want the ground very rich, very soft, and friable. We want it so it will spade up and tumble down fine about as easily as you would spade up the peat in a peat-swamp. We want an admixture of sand and clay, however, to make it heavier than peat, for we can not well have it work quite as easily as peat. This plan of gardening is for cabbage-plants, tomato-plants, lettuce-plants, celery-plants, and all other plants that are called for, besides early lettuce to come first into market, a few extra-early cabbages, a few hills of cucumbers, to be forwarded by means of hand-glasses, to be described further on; early cauliflowers, beets, and onions, and, in fact, a little of almost every thing that you have learned by experience will bring a big price, or a price big enough to warrant more expensive hand-work in order to get it first into market.

This plant-garden may occupy from one-sixteenth to one-fourth of an acre, according to your market and requirements. It should be protected from winds by buildings, or tall tight fences on all sides but the south; then it should be most perfectly underdrained, or, better still, fixed on the plan of the new agriculture, as I have described in Chapters V., VI., VII. The ground should be manured to a depth of two feet, or three feet if you can manage it. It should then be worked up so light and fine that, when you step on it, your foot will sink in the soft earth; and when you get it just right you should put some long boards between the rows of plants to walk on, to prevent tramping the soil down hard while cultivating or gathering the crop. You can easily tell when the soil is in such a condition that it will be injured by walking on it. The amount of rain has something to do with it. Then, as soon as you can, if you are not near a town or city where water-works are accessible, you should have a tank, with rubber hose attached, to water your plants, or whatever else is in danger of suffering from want of moisture. As a rule, water is seldom if ever needed to bring forward the crops where the ground is in proper order, and sufficiently rich with manure. But there are times when it is desirable to set out plants, even during a spell of dry weather. In such a case we want to take our rubber hose and saturate the ground thoroughly where the plants are standing, as well as the ground where they are to be put out. If you have facilities for doing this, you can transplant right in the midst of a dry time in August, without losing a plant or stopping their growth. Having a hose so that you can flood or sprinkle every foot of your plant-garden when it is needed, is a great advantage. If you get water from the public water-works, you can usually buy it at so much per 1000 cubic feet. If you have an elevated cistern in or on the upper part of a building adjoining your plant-garden, you can catch sufficient rain water so it will not cost you any thing, and this, perhaps, is the cheaper plan.

A wind-mill pump, to draw water from a well, answers nicely, providing you can get plenty of water without going too deep. I should prefer the rain water, could I have my choice. This plan of garden ought to be located near a public road, so that you may get the plants cheaply and quickly when somebody calls for, say, only 5 cents' worth. It should be located near the dwelling-house, or near your shop or office, so that, no matter when somebody calls for the plants, some one of the household or establishment may be in readiness to wait on the customer at once. Having the back door open directly into the garden is an excellent plan. To manage this nicely, your dwelling should be on the south side of a road running east and west. Our factory is thus located, and this gives us a nice shady place to keep plants in view of passers-by, on the sidewalk, on the north side of the building. Boxes of freshly transplanted plants are thus in the shade until they get well rooted.

At the right of the picture you will get a glimpse of the greenhouse, shown on page 142; and at the left, in the foreground, a view of the cold frame, shown on page 139. The plan of the beds is about as it appears in reality, only the artist has greatly enlarged the pictures of the cabbages, lettuce, beets, etc. Three feet of each bed, next to the path, is occupied by plants of celery, cabbage, lettuce, etc., ready to sell to customers. The pair of stairs, of which you get a glimpse near the upper right-hand corner, leads to the store belonging to our factory, making it very convenient for any of the clerks in the store to go out and get plants whenever they are ordered. The operation is briefly like this: A hose is attached to the water-works near the greenhouse door. This permits it to be used inside of the greenhouse, or in any part of the plant-garden. When a customer wants



A ROUGH SKETCH, OR A SORT OF BIRDSEYE VIEW, OF OUR PLANT-GARDEN.

plants, the clerk catches up a paper bag large enough to hold the quantity asked for. He then goes out, catches up the hose, turns the nozzle so as to spray the bed where he wishes to pull plants. If we are selling them right along, as we are at this date, the ground is kept pretty well saturated, and this is just what suits celery. Enough peat is intermingled with the soil forming the bed of the plants, so that, when the plants are pulled, their bushy and fibrous roots bring along peat enough to dampen them just about right, when they are put into the paper bag, and then handed to our customer.

The plant-garden is a very attractive place, because it is such a novelty to our town to see plants growing so luxuriantly, and so much in advance of the season. Underneath these plant-beds are reservoirs, described on page 58; and it is presumed that the cabbages and lettuce have already sent their roots down into the water of these reservoirs. Whenever we have sufficient rain to leach through the beds, the leachings of the manure go into these reservoirs, and remain until wanted by the plants. The cabbages you see in the cut now measure two feet across. They are of the "Jersey Wakefield" variety that never grow very large, so we are expecting some rousing heads before many days. Some of the heads of lettuce weigh 1¼ lbs., and measure 18 inches across. We get 15 cts. apiece for them on our market-wagon. We have been selling radishes for several weeks, raised on this plant-garden, and beets are large enough to go on to the wagon now. An acre of such ground, planted to cabbages, would, without question, raise a crop that would sell for $1000. Of course, it would cost something to construct the reservoirs, and buy manure; but I think it would pay near a good market for early cabbages in June.

The borders of the beds were mostly made in February, by driving down stakes and nailing on top of the stakes 2 x 4 scantling. Around the larger beds we nailed drop siding on top of the stakes, and had it afterward painted, to make it look tidy. The smaller beds were made in the same way, using any rough refuse boards to be found around the premises. Raising the beds from the ground makes it convenient to handle plants as well as to do the necessary work. The tender plants were covered with sash in February, but we hardened them gradually so that the sash was used very little during the month of March.

TRANSPLANTING.

One great secret of working this plant-garden is to understand transplanting so as to do it surely and safely. The plants are taken from the seed-boxes in the greenhouse, and transplanted into the soil of these raised beds by means of the transplanting-frame shown on page 136. It is a good deal more difficult to transplant in the open air than to transplant in the boxes kept all the time in the greenhouse. Drying winds are very trying to tender plants just put out. If these drying winds are accompanied by a scorching sun, you will find the labor of several days all gone to naught before you know it. As a remedy for this, they should be shaded for a few days, after being put into the open ground, with light shutters made the same size as your 3 x 6 sash; that is, these shutters, or shades, should be used when you see the plants are suffering from the scorching sun and drying winds. The shutters had better be removed at night, whenever dew falls, or on cloudy days.

Something answering still better than the shutters is a shading-frame made of lath, the lath being half an inch apart. This protects the tender plants from the wind, and enables them to get some sunshine; but as the shadow is always moving, they get alternate sunshine and shade, which seems to suit them much better. It is especially important that celery-plants have this partial shading. When some of our beds looked as if the celery-plants were pretty nearly all dead, ten days' covering with these frames brought them up to full vigor.

This plant-garden should be manured with the very best old rotted stable manure, and manured heavily. On one little bed, 6 feet by 20, we shall get, for a single crop of lettuce, perhaps $10.00. Two good loads of manure were put on to give this crop, which were worth perhaps $2.00. The manure was thoroughly forked in, so that we have nearly or quite two feet of soil that will give an immense crop at almost any season of the year. Now after having put so much expense on a little piece of ground, this piece of ground must be kept constantly cropped; yes, winter as well as summer. As soon as the lettuce is off, put in beets, radishes, or plants, and keep it going; and along in the fall fill it with cold-frame cabbage-plants, and keep it doing something right through the winter. Some of the papers are inclined of late to call plants raised very early in the spring about as good as the cold-frame plants; but I tell you, friends, they are nothing like them. Our cold-frame cabbage-plants that have stood heavy freezes over and over again will stand drought, insects, and almost any thing else, in a way that plants not so hardened can not do. The same is true of lettuce-plants. The hardened cold-frame lettuce-plants are ready to boom when plants taken out of the greenhouse would shrivel up and die. It is true, plants may be taken out of the greenhouse, and hardened off in cold frames, say in February; but we think it a good deal less trouble to get good strong stocky plants in the fall, and keep them so all winter. Now, then, let us remember that this plant-garden is to be made to work every week in the year.

CHAPTER XVI.

Whatsoever a man soweth, that shall he also reap.—GAL. 6:7.

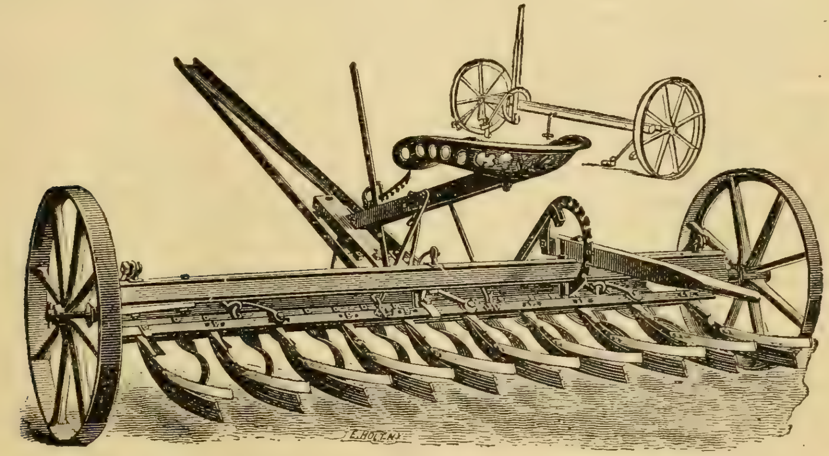
We are now ready to consider the growing of crops on a larger scale than heretofore; and as these papers are written mainly for those of but limited means, as I have remarked before, they may not, perhaps, apply to all of you, although the general principles are the same, whether you work on a large scale or a small scale. Many who are out of employment have no ground of their own, not even a little patch big enough for a plant-garden; but it seems to me one of the first things I would aim at, if I were so situated, would be to get a little piece of ground of my own. I would cut off some of the luxuries in the way of food and clothing, in order to save enough to buy a little piece of ground. And now I hope you will not think I am striking off suddenly into a piece of eccentricity when I say that this piece of ground should be in the form of a *long strip.* It is true, it takes more material to make a fence to inclose a long strip of land than it does to inclose a square lot; but for all that, we want the long strip. If you can get a piece of ground for a plant and vegetable garden half a mile long, you are a lucky fellow: if you can make it a mile, you are still more lucky. Do you want to know why? Well, read the following extract from Landreths' price list:

IMPORTANCE OF HAVING YOUR GARDEN LAID OUT IN LONG ROWS.

The old style of gardening, laid out in squares, to be dug and cultivated exclusively by hand, is becoming a thing of the past. The vegetable-garden is now laid out in parallel rows, or drills, ranging from two to three feet apart, and the cultivation of the greater part is done by horse power, as has been so frequently taught. The site should be the best obtainable with reference to the soil, exposures, and topographical features; the area should be large, and every thing done upon liberal and practical principles; the seeds should be all sown in drills, or rows, so as to be adapted to horse culture. Hand labor is the dearest of all, and should be avoided. The land, if circumstances will permit, should not be of a less length than 75 yards, and may with advantage be extended to 200, according to the quantity of vegetables required. Long lands, where animal power is used, are much to be preferred to short fields, as much time is saved in turning; for example, a plow team in a journey of eight hours, plowing land 78 yards long, will spend 4 hours and 39 minutes on the head lands; if the furrows were 274 yards long, the time spent in turning would be but one hour and nineteen minutes. The tillage of the garden should be the most approved labor-saving implements, wheel-hoes for hand use, scarifiers and cultivators for the horse. The seed should be sown with hand-drills, and fertilizers of the guano class applied with a similar apparatus, and, without interfering with the labor of the farm, be made to yield vegetables in profusion, when, if the spade and hoe are relied on, they are produced in stinted quantities. The amateur gardener, and expert as well, should make out a list of the varieties of vegetables he desires to have, and then lay off on paper a diagram of his garden, assigning certain rows to each sort.

Just think of it, friends! Four and a half hours out of eight may be spent by an expensive man and team in simply turning around his horses; whereas, by a little different management, these four hours and more of the hardest and most fatiguing part of the work may be reduced to one hour and nineteen minutes! Do you know why everybody hates to plow a garden? It is because there is so much turning around to be done. This turning around is so trying to the teamster that he loses his temper, and calls his horses "fools" or worse names. The horses doubtless lose their temper because they can not see any reason for so much pulling and hawing about; being called fools and idiots because they do not understand nor comprehend, and like phrases. I once heard a man complaining that there was not a teamster in Medina who would plow a garden for less than $1.50.

He thought the price was next door to swindling. Well, I presume the teamster did not want jobs of plowing village gardens, even at that price. Terry takes up this matter with great vehemence in a chapter or two of his Potato-book; and this little book has been the means of making a reform in this very matter. The objection to plowing land in long strips has been urged, that many farmers want to plow their land in one direction one year, and at right angles to it the next year, to keep the ground level. Well, if this must be done I would have my fields half a mile square—if I could. I have sometimes thought I should like a field so long that I could start down one row after breakfast and get back on another just about dinner-time. The horses would have to turn around but once in the forenoon. I do not know but I could afford to stop and get a drink of water, and give the horses some, at this one turning; and if I turned near a public road, and a neighbor should come along, it might not be out of place to chat with him, say five or ten minutes before I started on the back track. On our ten acres here at the Home of the Honey-Bees I have been greatly tried and vexed because so many of the men I hire would want to stop and visit every time they came to a place to turn around—especially if that turn-around happened to be near a public road. I do not like turning around, any way you can fix it. It is vexatious and trying to the horses as well as to the driver, and it is a shameful waste of time. We almost always plow around our piece of ground, and harrow around it, in order to avoid, as much as possible, turning squarely about. It is much easier for the team to make half a turn than to make a complete turn clear around; and when horses are tired I can see from their very looks and actions how they dread being pulled right squarely about while some awkward piece of machinery has to be pulled and hauled around also. Within the last few days we have had a pair of wheels put on our Acme harrow, so that, whenever we have to turn abruptly, we can, by means of a lever, raise the knives clear out of the dirt, so it turns as easily as a cart; and I tell you it is a relief to me, I am sure, and a relief to the horses. This Acme harrow on wheels, or with a sulky attachment, as it is sometimes called, pleases us so much that I will give an engraving of it.



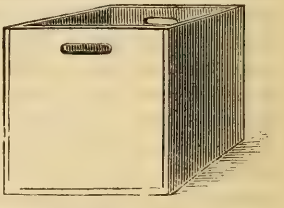
ACME HARROW WITH SULKY ATTACHMENT.

The wheels can be attached to any Acme harrow already in use. I prefer the Acme harrow to any other I have ever used, because of the cutting motion of the knives, which chop every thing up, but never catch and break the machine, or jerk the horses unmercifully. You can run it over roots or stones or brush, long manure or corn-stalks, and it cuts them to pieces like taking a long butcher-knife and slashing it repeatedly across the article to be worked up fine. You will see these knives will run over soddy ground, and work it up fine without turning up the sods or turning them over. It simply cuts them in pieces, and lets them lie where they are. By means of the lever right before the driver, the knives are instantly pulled clear off from the ground, so that you need not cut up the soil when you don't want to. By moving the lever either way you raise the *wheels* clear off the ground, thus putting all the weight on to the knives, so as to make them go down deep. By repeated harrowing you can get the soil so fine and soft that the knives run in the dirt clear out of sight, moving it about, reminding one of water behind a propeller-wheel. While we are on this matter of turning around with a team, I want to speak of something akin to it. It is what an old friend of mine calls

"TURNING-AROUND GROUND."

This turning-around ground is a space of twelve feet, without any thing being planted on it at all, at the end of every piece of ground. He claims that it takes 12 feet to turn about the horses and cultivator, and that it is economy to plant nothing on this twelve-foot strip. In fact, he recommends that every market gardener have a road twelve feet wide clear around his whole farm ; and this road, at the ends of the rows, is to be used for the turning-around business. It lets the cultivator go clear up, or pretty nearly up, to the last plant, and it lets the horses turn about and start in the next row without stepping on any thing. I do hate to see nice crops trampled down by horses. Well, I have carried this doctrine of the turning-around ground a little further by plowing our land so as to throw the rich vegetable mold from this twelve feet right over on to cultivated ground. At one place, where the ground was remarkably rich, I had it shoveled off clear down to the yellow clay, and over on to the land adjoining, giving me 15 or 16 inches of rich vegetable mold, instead of 7 or 8 inches.

Now, then, if you have got your long strip of land planned for big crops, let us carry out some principles on it we had in our greenhouse beds and our plant-garden. Make the ground clean, level, and free from stumps or stones or trees. Shade-trees are nice in their place, but we don't want them on ground that has been manured up to the standard for market-garden stuff. The trees must go or the vegetable-garden must go. Neither can we have stones in the way to bump the plow and cultivator, and rasp one's feelings when he is tired, and disposed to be cross. I would pick up every stone the size of a hen's egg, or larger. By the way, when I was a small boy I used to think that picking up the stones off from a field was the dryest, dullest, and most monotonous work I ever endured. Do you think it is any thing very wonderful if I find that the small boys and small girls who come to me and want work feel the same way now, about picking up stones, roots, etc., scattered over our grounds? Perhaps not; but somehow or other I enjoy this work so much now that I just feel happy to go out with the children and pick up stones. Yes, I feel happy to go out and pick up stones alone, because I feel that every pebble got rid of from my ground makes it just a little bit nearer to perfection. I have figured a good deal in regard to picking up stones. Last year we used Terry's potato-boxes, such as are figured in the adjoining cut.



TERRY'S POTATO BOX.

I would tell the small boys and girls who were asking for a job, to carry a lot of these potato-boxes out into the field, scatter them where they would be handy, then fill them with stones, or, at least, put in all the stones that were very near the boxes. Then a man with a stoneboat went around and lifted the boxes on to the stoneboat so he could draw them where they were wanted. Do you ask where the stones *were* wanted? Why, you will find the place by turning to page 58. The way we gather stones now is when we are rolling the ground. We have an iron roller drawn by two horses, with a stout plank box on top, made with sloping sides. A man drives the horses, and three or four children follow along to pick up the stones and pitch them on to this plank box. The box is ironed strong enough so the heaviest stones they can lift won't hurt it. Some way the children seem to enjoy it better to work along with a man and a team. When the roller-box gets full we drive to a reservoir left open on purpose to take the stones, and the children have the fun of pitching them into the water. We have just been clearing the field of stones, down across the creek. There is no place handy to put them, but I remembered a hole where water stood most of the year. I had one of the boys dig the black mud out of the bottom of this hole, and throw it up around the sides. Then we put all the stones they could find into the hole and covered it, according to the plan of the new agriculture, with flat stones and tinware, and then raked the black mud and dirt that was shoveled out, back over the stones, and we now have level ground on which to raise crops with the new agriculture underneath it. Almost every piece of ground has low places enough to take up all of the stones, and the work is not very hard nor very expensive either. If these who do it enter into the spirit of getting rid of the stones, filling up holes and getting the rich decayed leaves usually found in such sinkholes upon the surface, they won't consider it very hard work. Some of our boys thought it was a little hard to go down into this nasty mud, but I furnished them a pair of rubber boots at my own expense, and we don't find it disagreeable, unless it is the nasty smell that arises when such places are shoveled out. I rather like the smell, because it reminds me that valuable fertilizing material is stowed away there.

While speaking of the roller, I might remark that we consider the tool a very valuable one when used judiciously. It should never be run over plowed ground, however, unless the soil is so dry that it packs it no more than to mash up all the lumps, and level the surface. To get ground real nice for setting out plants, or for almost any other purpose, we go over it with the roller and Acme harrow alternately. Roll it twice and harrow it twice, and your ground ought to be in beautiful order for sowing the seed.

By the way, perhaps you would like to know how I like to see the ground prepared for sowing seed or for setting out plants. But before describing my plan I want to say that you will have to be governed a good deal by circumstances—the implements at command, the size of your land, etc. Ground that has been plowed the year before, as soon as it is dry enough, we go over with the Acme harrow, then roll it until it looks as if it might do very well for sowing the seed. Well, when the ground is soft and fine and nice on the surface, we go over it with the manure-spreader, and spread twenty loads to the acre, of the best manure we can find; then the Acme harrow goes over it again, and stirs the manure well up with the surface soil, until the ground is fine again. It is now ready to be plowed.

In regard to plowing the ground, I suppose almost any old farmer can tell you more about that than I can, if you do not know it already. We want to do a nice job at every step, and we want nice plowing to begin with. After it is plowed nicely, go over the same operations again; *i.e.*, harrowing it with the Acme harrow, rolling it, picking off the stones, harrowing it again, another putting-on of manure with the manure-spreader, another thorough harrowing; then, if the ground is dry enough, finish with the roller, and you are ready for putting in the crop. I have practiced subsoil plowing to some extent, but so far I have not seen any very great advantage resulting therefrom.

The entire difference between loss on the one hand and gain on the other, may depend on a little management. During these beautiful growing days in the month of May it is of the utmost importance that your work move right along without any hitches or breaks. If you are going to succeed, you can not go visiting very much, nor attend picnics or excursions. If you are going to be guided by me, you must get your happiness from your work. Your mind should be keeping pace with your body. Plan all your work the night beforehand, so as to be ready to take right hold as soon as you wake up in the morning. When you get through using one machine, have your mind fully made up what one is to come next. Decide whether the whippletrees, neckyoke, and clevises are all where you want them. Don't go off across the farm to hitch on to a tool, and find you have forgotton the doubletrees, and then have to go back after them. I have known men who would get the doubletrees, and then would go back again to get the neckyoke. If you work in that way you will surely fail.

Another thing, doubletrees and whippletrees frequently break. I do not know that it is practicable to make them so they won't break. It might be done, it is true; but you would have to have them so heavy that you would probably lose in another way in the end. But, be sure of this: That there are surplus whippletrees ready to be put on at a moment's notice. I would also have surplus bolts and burs nicely put away in the tool-house, or wherever your tools are kept. Have oil-cans, and tallow also, in readiness, to keep all your tools in good working order. Be sure that wrenches, suitable for the work they are to do, be in readiness near by, and make it your business, sleeping or waking, to be ready to push ahead in spite of accident and emergency.

When the weather is fine, decide exactly what you are going to do the moment it rains; or, if you keep a hired man, have work saved up in readiness for him during a rainy day. Do not, under any circumstances, let him do work during beautiful weather that can just as well be put off until a rainy day. Hired men will do these things unless you keep a careful watch on them. Neither will it answer for you to set a big strong man at something that a woman or child could do equally well. The brisk competition that is now kept up in all kinds of business is such that you will surely fail if you are guilty of this kind of folly. There may be circumstances, it is true, to justify doing differently from what I have just intimated; but bend your whole energies to the work of deciding how you can accomplish most with the least expense. Do not put great stout horses on work that can be just as well accomplished with one horse, and a light one at that; and don't set a great stout man at something that a child can do better and quicker. Children enjoy work if their work is planned wisely for them; and they are far happier when doing good somewhere, than if left to their own devices.

Perhaps you object to all this fuss to get your ground ready for a crop. Well, it is true you can go along and put in your seed after the usual plan, and raise a crop; but, my friend, if you are going to raise a crop that will bring you $1000 for the proceeds of a single acre, you have got to put labor and capital on that crop. To-day our market-wagon is selling heads of Boston market lettuce at the rate of forty or fifty a day in our small town of only about 2000 inhabitants. The largest heads bring from 10 to 15 cts. This morning I myself cut two heads that weighed 1¼ lbs. each. Now, we have never been in the habit of using very much lettuce at our house. My wife has often objected, because it was so much trouble, especially when I brought in a lot of lettuce just before breakfast was ready. Since we have got to having single heads that weigh a pound, however, she says the case is entirely different, for all she has to do is to strip off a few of the outside leaves, and the interior of the head is cleaner and nicer than any washing can make it. It is no trouble at all to fit it for the table, and I can assure you it is no trouble to dispose of it after it is on the table. The secret of getting these large, beautiful, crisp, delicious heads of lettuce is, however, fine tilth and lots of manure. Such heads of lettuce can be easily raised for the market so as to be ready every day in the year; and I imagine it would be a pretty hard matter to overstock almost any market. Here is a crop that will bring you money every day in the year, and yet it has almost no insect enemies, and is almost sure if you have your ground in proper order. Now, what do you suppose an acre of such lettuce will bring? And after you get your ground in trim to raise heads of lettuce that will weigh over a pound, on every square foot of its surface, it will yield an enormous crop of any thing. Just figure up the number of square feet in a mile; cut off one figure, and you have the number of dollars per acre that your stuff ought to sell for. Very likely you urge that no such an amount as an acre will grow or can be sold in a locality. That may be true, and then it may not be true. When you get more than your home market will take, just send samples to the right kind of a man in some large city. As an illustration: We found we had more "Jersey Wakefield" cabbage-plants than would be wanted in Medina. We did not write to the city of Cleveland to see if they wanted any. We simply sent a basketful of plants for their inspection. Here is what the commission house wrote:

> The cabbage-plants are rather large, but they were taken readily. We can allow you 30 cts. per 100 for cabbage, and $1.00 per 100 for tomato. You might send us 500 cabbage-plants next Monday, if prices suit you, and about 200 tomato. But we need Acme, not Trophy. A. C. K.
>
> Cleveland, O., May 6, 1886.

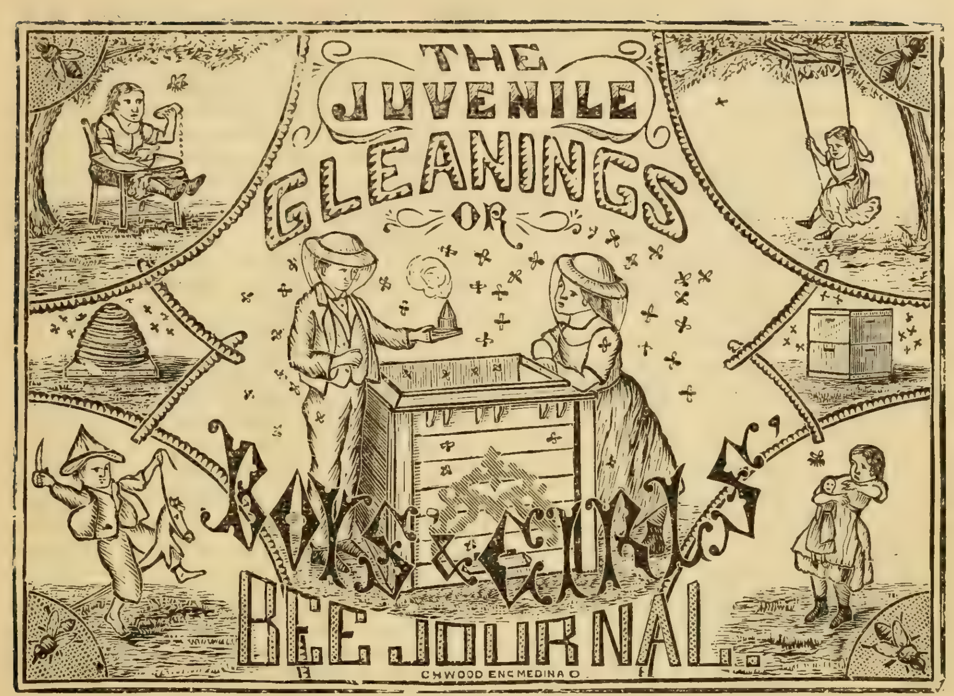
A few days after, comes the following:

> Please express at once 300 Acme tomato-plants at $1.00, and 500 Wakefield cabbage-plants at 30c.
>
> Cleveland, O., May 11, 1886. A. C. K.

Now, friends, please figure out the profits on an acre of ground devoted to cabbage-plants or tomato-plants, at the above prices. It is true, you will need the aid of a greenhouse, cold frame, or hot-bed, for plant-growing; but these are not difficult to command. Please don't imagine, now, that I advise every one to go to raising lettuce, cabbage-plants, and tomato-plants. That is not the idea at all; but I do recommend that you who are out of employment, spending your time in loafing, or something worse, do get hold of a little piece of ground somewhere near you and make it give up the treasures God has wisely placed within your reach.

We will suppose your ground is underdrained (or, better still, fixed something on the plan of the new agriculture), nicely plowed and harrowed, stones picked off, and every thing ready for the planting of the crop. How shall we put in the seed?

To be continued June 15, 1886.



He that is faithful in that which is least, is faithful also in much.—LUKE 16:10.

MYSELF AND MY NEIGHBORS.

Thinketh no evil.—I. COR. 13:5.

WELL, friends, here it is along toward the first of the beautiful month of May. The apple-trees are in bloom, the bees are rejoicing, and the weather is so fine that it seems to me every boy and girl ought to be ashamed of themselves if they can not rejoice also. We have not had a bit of frost for several weeks; in fact, we have 2000 tomato-plants growing nicely out in the field, and some of them are more than a foot high, and covered with blossoms. A great many old heads are shaking wisely, and they tell me I will "catch it." But I am willing to take my chances. If the frost comes I will do the best I can to save my plants; and if I *don't* succeed, I am going to be happy any way. There are plenty more fine ones in the greenhouse. for a reserve to fall back on.

Well. it seems to me the bee-friends are busy and rejoicing too, for orders are coming in as briskly as we ever saw them before at the Home of the Honey-Bees; and, as a consequence, great numbers of neighbors are all round about me; in fact, for a few days back it has seemed as if it were my great privilege to give work to almost every one who applied; that is, with the usual promise not to drink, swear, nor use tobacco. There are so many of them, that I have some in my employ whom I could not call by name if I should try to. This brings me to what I want to say to you to-day.

Since we have put down the price of foundation, it has made a big boom in what we call the "wax-room." It is almost as full as a schoolroom now, and most of the time it is almost as quiet and orderly as *some* schoolrooms. The wax-room is mostly in the hands of girls and women. Mr. C., who has charge of it, says he does not believe it is, as a rule, a good plan to have many small boys and small girls together. They get to be so bubbling over full of fun that they can not attend to their work as well as if the boys were kept out, or in a room by themselves. With the older hands it does not make so much difference—that is, when they are old enough to behave themselves like ladies and gentlemen. In that case, I have sometimes thought that it was an excellent plan to have the sexes together. Well, with the rush of business in the wax-room, and the number of hands employed, there are more or less complaints of mistakes, about inferior quality of work, etc. Several times customers have complained that the base of the cells is not thin enough. This is caused by running the machines with the rolls too far apart. The other evening the man who makes foundation-mills told me that there were too many hands turning the adjusting-screws to the rolls. I told him I thought no one ought to touch those screws except the foreman of the wax-room. He said he had spoken to him about it, but that he replied something like this:

"The girls complain that the rolls turn too hard, and then they loosen the adjusting-screws, because that makes the rolls turn easier.” Of course, I was quite vehement about the matter, and I declared if we couldn’t find some way to make the girls *obey orders* it would be funny. Next day a piece of foundation came by mail, the letter saying that a ten-pound box we had just sent was all like it, and that he couldn’t use it at all, because it was too thick at the bottom. I took the letter and started for the wax-room, with a determination to straighten things up *thoroughly*. When I got down one pair of stairs, something began to say, “Be careful, Mr. Root. Remember what you profess, and bear in mind that the saving of souls is a thousand times more important than having foundation just as it ought to be, even though it is, without question, your duty to be faithful and honest to those who send you their money.”

In answer to the above, I thought something like this:

“Yes, this is all true; but this is a serious matter, and one that has come up over and over again, almost every season, and it needs to be straightened up *decidedly*.”

The still small voice ventured, as I was going down the second pair of stairs, something like this:

“Well, in any case will it not be better to be *very gentle*, and find out first whether there is not some mistake about it?”

I had been taught by so many, *many* cases similar to the above, that it is *always* safe to be very mild and gentle, that I concluded I would, although I didn’t feel like it. I asked the foreman of the room about it, and he laughed a little, but said that at least one of the charges was a mistake. He didn’t say that he couldn’t *make* the girls stop turning the adjusting-screws. He is a good Christian man, and, seeing by my face that I was disposed to be gentle and kind, he suggested that I should go and talk with the girls about it. Just now I want to confess, that, since my health has been failing, I have not been in the wax-room very much, and perhaps the same is true of a good many other rooms. As soon as I came among them and saw the crowd of anxious faces, many of them being comparatively new to me, I felt ashamed of myself right away. I pleasantly asked them some questions about making the foundation thin; and when I reassured them so they could talk freely, I discovered that they had been having a good deal of trouble and worry just because they could not get foundation to come off the rolls without tearing, and have it as thin as they knew we wanted it. One of them said, “Why, Mr. Root, we have wasted so much time in trying to get the wax to come off without tearing, from this little mill, that we really felt as if we must do something to prevent robbing you by charging for our time when we accomplished nothing. By turning the screws up a very little we could make it come off nicely. See. Don’t you call this sheet pretty fair?”

Well, it was “pretty fair,” but not quite what many of our customers would like, in the way of a thin base. My informant added: “But, Mr. Root, as soon as we got this last mill” (we had that day been obliged to add still another mill to keep up with orders, and this last was one of our finest brand-new ones) “we have no trouble in making beautiful foundation. Just see what nice work they are doing with it.”

So you see, dear friends, that the trouble was not with the girls at all, and it was not with the foreman; but it came from a mill that sometimes had a way of acting badly. May be you have seen machinery given to such tricks. I replied that they should have the nicest mills that could be made, and plenty of them too, for we could not afford to waste time on any thing short of the best.

Now, then, what a sad, sad thing it would have been had I been hasty, and gone in among that anxious little crowd, and scolded and found fault when they were doing the very best they could, and were worried and troubled because they could not do any better. Why, it would have been a cruel, *cruel* thing. And suppose one of them should have felt in her heart (for I am sure she would never have spoken it) “That Mr. Root, who talks so much in the prayer-meeting, and writes such nice things in his bee-journal, is, after all, a cross, hasty, and unreasonable man.” As I think of it, I can only say over and over again in my heart, “Thank God, thank God for the promptings of his holy Spirit that bade me be gentle and charitable while I was going down those two flights of stairs.” Why, when I look into my own heart, and see the great heaps of uncharitable feelings that lurk there, ready to burst forth, and ready to jump at conclusions upon the slightest pretext — ready to imagine that everybody is evil, and lacking in conscience and truthfulness, it appalls me. May God have mercy on me a sinner; and may his holy name be praised that he has taught me to hold on, and to put a check on these feelings, that they may not come out and do harm; and may his great love so fill my heart that there may be no room for even uncharitable thoughts. May kindness and love toward all humanity, toward the stranger within our gates, as well as those who have known me intimately and well, help me to remember the little text at the head of our chapter, “Thinketh no evil.”

FROM JAPAN TO PENNSYLVANIA.

AN INTERESTING LETTER OF THE JOURNEY, BY THE SAME LITTLE GIRL WHO TOLD US OF JAPAN TWO YEARS AGO.

DEAR MR. ROOT:—What do you think has become of your young Japanese (?) friend? or have you given the matter much thought? I had intended to write to you of our expected departure from this “Sunrise kingdom,” but on account of being so busy with our preparations for the same I was unable to do so; and when we got here I entered school, which, though quite novel, was equally a busy experience. As we are having a week of vacation at present, I have taken this rainy afternoon to write to my old friends of the adventures I have experienced since leaving Japan last October.

Our voyage, which lasted about 17½ days, was delightful—the last day especially being interesting, on account of the shoals of porpoises which raced with the ship, the groups of whales spouting in the distance near the coast, the flying fish, sea-serpents, and, most of all, the sight of dear old America, though the first glimpse was of the bare sides of the hills bordering on the coast.

After a few days of visiting at San Francisco we started on our journey across the continent. After we left the great ranches and enormous trees of California, the scenery following was quite uninteresting. The Nevada plains and hills were studded with clumps of sage-bush which soon grew monotonous; but the Great Salt Lake in Utah was interesting, and *I* thought pretty. The mountains on the opposite side showed signs of breaches quite near the summits.

We noticed some very curious and beautiful cañons, waterfalls, and glens, in the Rockies; but we passed some of the most noted during the night.

I thought Indiana's rolling surface, large groves, and romantic scenery a lovely contrast to the dreary, treeless plains of Nebraska and Kansas; but when we came to Ohio I was charmed, especially with Cleveland, the Forest City, where we spent a short time. I went around the city a little, and saw the great aqueduct, which cost several millions of dollars; and we saw the cemetery where Garfield is buried; and we also saw beautiful Lake Erie.

I wish I could visit you at Medina; but circumstances were such we could not stop, and we came on to the "Knickerbocker" State, with its great farmhouses and whitewashed fences which really struck me first.

I entered school in the beginning of January, and have enjoyed my first school life exceedingly. I am attending a seminary for ladies and gentlemen, which is under the auspices of the church. The teachers are all very pleasant, and we have strictly moral influences. The name is Schuylkill Seminary, and it is at Reading, Berks Co.; next fall, however, it is to be moved to Fredericksburg, Lebanon Co., where mamma expects to settle down.

With kind regards to your family, and best wishes for the prosperity of your magazine and business, I am as ever, sincerely yours, **Ada M. Krecker.**

Norristown, Pa., March 29, 1886.

Some of our readers will remember that this same little girl wrote a letter over two years ago in regard to the life and customs of the people in Japan. We also had an engraving made at the time, of a Japanese lady riding in a "palanquin" (see page 127, 1884). We are glad to welcome her back to this country, and hope she is educating herself to go back to a life of service for the Master. **Ernest.**

HOW A LITTLE GIRL STARTED IN BEE-KEEPING, AND SUCCEEDED.

HOW SHE MANAGED 5 SWARMS OF BEES THAT FLEW OUT AT ONE TIME.

FATHER has kept bees for eight years. Three years ago he said if I would take the bees and racks out of one hive, and put them in another hive I could have them, when I got them out. He told me to put them back in the hive I took them out of, for they would not go into the other hive. This hive then was mine. They did not swarm that summer. The next summer they swarmed twice. The last time they swarmed, father and mother were away from home. While they were gone, five stands swarmed. I got two to alight; two I threw water on, and drove them back, and mine I threw water on. The bees got nearly all out when the queen came out. I ran into the house and got two tablespoons and caught the queen between the two spoons, and the bees went back. That winter one of my stands died. Last summer they swarmed twice. One day last summer there was a swarm came here. Father said if I would hive it I could have it. This I did, and I had four stands then. These made about 80 lbs. of honey. Father got about 3000 lbs., nearly all comb honey. He put 77 stands in the cellar, and they are wintering well. We take Gleanings, and mother says she can not get along without it.

Grace Jewell, age 14.

Shell Rock, Butler Co., Iowa, Mar. 26, 1886.

Thank you, friend Grace, for your very excellent report. You are the first one, if I am correct, to demonstrate the soundness of Mrs. Harrison's suggestions (see p. 317; i. e., that the children have bees of their own) and report what *they* have done with *their own* capital. I don't think your father regrets at all giving you the swarm, on the condition that you could accomplish a certain thing with them; and now you are able to perform most of the operations in the apiary successfully. I doubt very much whether one of the veteran bee-keepers could have managed those five swarms as well as you did, and your report of how you managed them is certainly interesting. You say that you drove back two swarms with water. Did you use the spray of a force-pump, or did you simply dash water on them with a dipper? I should also like to know how quickly the swarm returned after you gave them a shower-bath. You know it is doubted by some whether throwing water has any effect in inducing the bees to cluster. — Your queen-cage of two spoons is quite novel. It seems to me there would be some danger of killing the queen. However, in your hands no doubt it answered very well. You have done so well that I think you certainly deserve a chromo, and an extra nice one too. I have told the mailing-clerk to send you one. Let us have other reports from the little folks who have bees of their own. **Ernest.**

FACTS FROM ACTUAL EXPERIENCE AND OBSERVATION.

FROM OUR YOUNG FRIEND CHARLIE.

FRIEND ROOT:—Bees wintered well here, and are now in fine condition. They began gathering pollen March 18 and 19, but have gathered very little since, on account of so changeable weather. We have been feeding some. We had one weak swarm run out of honey one night, and the next morning I brought a part of them to life by warming them, but they did no good.

One evening, a short time ago, we moved a swarm two miles. When we fixed them up the bees were spread about, all through the hive. After we had got them home, sawed the entrance large, and in other ways badly jarring them, we looked into the hive, and were surprised at finding them drawn up into winter quarters, and any amount of thumping and pounding failed to make a single bee move.

Now, do bees generally act so decent while being moved? Last winter we moved some swarms but one-fourth of a mile, that became badly demoralized. We wintered two large swarms this winter, with entrances only 2½ by ⅓ inches; and in spite of so little ventilation they came through, losing scarcely any bees. In some hives, upper ventilation right above the cluster was used all winter, without causing any harm.

We have over 40 varieties of honey-plants near us. The mallow, which blooms as late as November, is the latest. It has short leaves, flowers variegated with white and pink, and it produces snow-white pollen. Ironweed produces white pollen, and the bees get covered with a white dust while working on it. Bees do not work on red clover and goldenrod here, as the blossoms of the latter get so destroyed by the old-fashioned potato-bug, or, may be, because the bees do not notice it. Hawthorn, four kinds of smartweed, and several species of autumn flowers resembling sunflowers, are good honey-plants.

It is queer indeed how bees find out honey so quickly. One day last spring the cellar-doors were left open. Some honey was down cellar. I was near by at work, and I did not see a bee anywhere about. Presently I left, but was back shortly after. The cellar was just swarming with bees. I closed the doors, and the bees came out of the cracks. This started robbing. I find that bees are more apt to fight on damp cloudy days than on bright warm ones. On autumn mornings they often all mix up in a big fight, but quiet down when it gets warm enough for all to go to work in the fields.

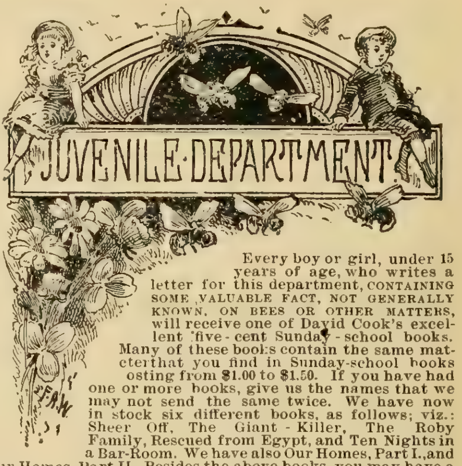
Fall before last a great many bee-trees were cut down. One was said to contain 200 lbs. of honey. Last fall, not one was cut down.

The morning of June 27, 1885, was a bright one; but at 10 A. M. it began raining, and rained until 3 o'clock. The clouds then broke away, and the bees went to work. One swarm I noticed was unusually quiet. On looking into it, it was found quiet inside also. Presently they began rushing about, and so they were shut up. Then they began swarming. When they clustered the limb was sawed off and taken to the new hive. While doing so a small bunch dropped off. When the swarm was hived we looked and saw that the bunch that had dropped off had risen up and clustered on the tree close to where the swarm had clustered. Part of them were brushed off and carried to the hive, and the rest were shaken off. These then struck directly for the new hive, which was not over a rod distant. Now, this, although a first swarm, came out at 4 P. M., two hours past the usual swarming time. It may be likely that they prepared to swarm in the morning, and as the rain stopped them they had to wait until it was over, which made them quite late.

One sunny day last winter, when it stood only 23° in the shade, I placed the thermometer on the south side of a hive. It soon ran up to 83°, so it was 60° warmer on the south side of the hive than in the shade. **Charlie L. Greenfield**, age 14.

Somerville, Butler Co., Ohio, Apr. 5, 1886.

Very good, friend Charlie. Your thermometer was placed in the sun, and that is why it recorded such a difference in temperature. In taking such observations, the sun should never be allowed to shine directly on the thermometer, especially on the bulb.



JUVENILE·DEPARTMENT.
F.R.W.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matcterthat you find in Sunday-school books osting from $1.00 to $1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of nformation.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

WHAT TO DO, AND HOW TO BE HAPPY; A SEQUEL FOR THE WEE FOLKS.

CLATTER, clatter, whackity bang, tick, tack, click, clack — "What's all that racket this time of the day?" exclaimed I. The heavy machinery had all stopped for the night, and I was sitting at my desk, with pen in hand, prepared to write something *real nice* for the little folks. Racky tack, tick tack, cracky cracky whack! This only I received in response to my question. "What in the world *is* all that racket?" I thought. "I wonder"—racky tack, ticky tack, ker squash—"oh! I know; it is one of the clerks who has been working late hours to fill orders, and in his blundering haste has tumbled a pile of goods all over himself and on to the floor. How clumsy some folks are!"

There, there! in my uncharitableness I have just lost a *splendid* thought, and I can't recall—racky tack, tick tack. Half disappointed at the loss of a brilliant thought that wouldn't come back, and half bewildered at such an unseasonable din, I was on the point of saying, "Ma, make the children stop that incessant noise; I can't write, nor hear myself think," when I remembered that I was married now, and that I wasn't over home, nor was Blue Eyes, Caddie, or Huber, anywhere around to bother me as in days just gone by. "Ma, make them stop" has become almost a part of my nature, and it crops out once in a while now. Racky tack, tick tack. "Oh dear me! what shall I do? In this noise I can't think of any thing, and 'Barney' is calling for the 'Introduction to the juveniles.'" The noise seemed to grow louder. Half curious, half out of patience, I arose from my seat and sallied forth into the compositors' room, then through the long hall, and at last halted in the clerks' office. All was quiet, save that "racky tack." Following the sound of the noise I passed into the paper-room and bookbindery. I then sauntered into the sample-room. What do you think I saw? There were Hiram, Franky, Minnie—yes, and Ella too. Sitting at a table, each one had a mallet, and something to do. Sections, heaps of 'em, were they driving up square. Tick tack, click, clack, *that* was the noise everywhere. "What to do and how to be happy" seemed to be fully exemplified upon their bright happy faces, and I didn't feel a bit mad when I saw how rapidly and how nicely, too, they were folding together those one-piece sections we manufacture. It seems these children had seen what pretty work it was, and they had teased their mother, who has charge of the room, to let them do it too. As she was somewhat behind in her work, she consented to let them try; and when I saw them I was fully convinced that they were the best automatic section-formers I ever saw. Little 7-year-old Ella was keeping up with the older ones. How fast do you think she could fold them? We kept track, and found that she could fold a whole box of 500 sections in just about two hours. From the looks of her bright face I don't think she ever had any play that she enjoyed better. The question of "what to do and how to be happy" seemed to be fully solved for her. Now, I was wondering if other little folks couldn't do it too. I imagine that your papa, if he is a bee-keeper, has lots of sections he wants folded, and perhaps he has got a bright boy or girl who wants a job, and a chance to earn money. We pay 3 cts. per 100 for putting up sections in our factory. At this rate little Ella earned 15 cts. for the two hours she worked, or at the rate of 7½ cts. per hour. I think that is doing pretty well for a 7-year-old chick. Of course, she would get tired if she folded more than one box at a time.

Now, I do not know of any thing you can do at present that will help your father more for the coming flow of honey. I should like to have reports from the little folks, telling how fast you can put together sections. If you will do real well I will send you any thing you may choose from the 10-cent counter. ERNEST.

A PETRIFIED WASP'S-NEST.

My father has a petrified wasp's nest. It is about as big around as my fist. The cells are mostly filled up, and some of them are raised, while others are slightly broken. It looks a good deal like a honey-comb. He has also some with fern leaves on them. They are very pretty. CARRIE MELICK, age 10.

Waverly, Neb., March 30, 1886.

Now, Carrie, are you sure it is a petrified wasp's-nest? From your description I am inclined to think it is the work of some insects like the coral insect. Something in regard to this has already appeared in our back volumes.

AN OLD FOGY.

I read all the little letters and your foot-notes. Ma says that honey and croton oil (equal parts mixed), given every two hours in teaspoonful doses is the best remedy for the dysentery that she ever saw. She also has a dropsy recipe which takes a quart of honey to make it. We have a neighbor who claims to be an old bee-keeper. He says if he had a mind he could make all the neighbors' bees come to him and stay. Do you think such a thing possible? If so, is he not an enemy to bee-keepers near by, if he is not honest? TOMMY BROWN.

Searcy, White Co., Ark., Mar. 1, 1886.

Don't be alarmed, friend Tommy; that neighbor you mention has probably got a few old-fogy ideas in his head, one of which is that he could call all his neighbors' bees to himself. He might induce them to call on him for a short time by setting out syrup, or starting a cider-mill, but the bees, after they had feasted themselves at his expense, and had pestered him all they could, would return home without so much as saying, "Thank you." Nothing so much annoys me as to hear one of these old seers boast of the big things *he* can do. ERNEST.

THE NAUGHTY SABBATH-BREAKERS.

I wrote just one year ago, and told you about pa's bees commencing to carry in pollen on Sunday, the 1st of Feb. Now, these Sabbath-breakers commenced at work this year on buds of water-elm, on Sunday, the 31st day of January; so with all of our example and teaching we have failed to teach them better. LIZZIE L. MULLIN, age 10.

Oakland, Colorado Co., Texas, Feb. 17, 1886.

Thank you, friend Lizzie. It is true, the bees never respect the Sabbath; but working on Sunday isn't the worst thing they do. I have sometimes thought that Sunday was their favorite day for stealing and getting into mischief generally, and on holidays, when folks are not at home. Several times on coming home from church I have found the little scamps on a "regular tear," as the boys say. ERNEST.

HOW TO EXTRACT, AS TOLD BY JACOB.

When we extract we take the smoker and smoke the bees well, and then take the combs out of the hive. We next cut the cappings off with a knife, and then put it in the extractor. We then turn the handle around. But if larvæ are in the combs we have to turn very slowly. We turn until the honey is all out, and then take the combs out of the extractor, putting them in the hive again. We take the cappings off the combs, and then when we get enough we try them up and then take the wax down to the drug-store and sell it. We got 65 cts. for one pound nine ounces. JACOB BATTERSBY, age 11.

Port Dover, Ontario, Canada.

Your description is very good, and shows that you have had some actual experience in the apiary, aside from what can be learned in books. ERNEST.

HONEY AND ALUM FOR COLDS; FROM A LITTLE GIRL WHO LIVES AMONG THE INDIANS.

Honey, with alum grated into it, is good for the croup. I am an orphan girl. I live with Mrs. Thomas, and take care of little Ollie. We keep bees, and take GLEANINGS. Mrs. Thomas and I are going to attend to the bees this summer. Drones were flying the first day of April. Mrs. Thomas has given away a good deal of honey. We make candy of it too. LILLIE MILLS, age 11.

Stringtown, Choctaw Nation, Ind. Ter.

I presume you have Indians all around you, and that you do not find them so terrible as little folks are apt to imagine. By the way, if I am correct, the Choctaw Indians are the most civilized of any race of Indians in America. Missionaries are making every effort to get them started in agriculture. Now, can't you do a little missionary work, and get the red faces interested in bees? You can show them how delicious a thing is honey, and perhaps induce some of those who are not particularly fond of agriculture to start in bee culture. Unless I miss my guess, an Indian and his papoose have a sweet tooth somewhere. May we hear from you again? ERNEST.

A PRAYER FOR CHILDREN.

Inclosed please find a beautiful prayer, clipped from *Zion's Watchman.* My little brother and I have learned it by heart, and repeat it every night before we go to bed. Will you please print it in GLEANINGS, so that many other children may see and learn it too?

Father, now the day is past,
On thy child this blessing cast:
Near my pillow, hand in hand,
Keep thy guardian angel-band;
And throughout the darkling night
Bless me with a cheerful light;
Let me rise at morn again,
Free from every thought of pain;
Pressing through life's thorny way,
Keep me, Father, day by day!

Papa put out some rye flour for the bees to-day, and they worked on it quite well. My mamma does not think that honey is of any use for a cough or cold, where persons are used to eating it every day.

EVA GREGG, age 7.

Galilee, Wayne Co., Pa., April 2, 1886.

HONEY NOT GOOD FOR COLDS; MILK A REMEDY FOR "HONEY-ACHE."

In answer to your question, my mamma says she has been doctoring babies for 32 years, and never found honey of much use for croup. Honey is astringent, which is contrary for either colds or croup, and mamma says people should be very careful in giving it to babies. She was at a neighbor's house with her baby. A young woman fed it a little honey, and the babe soon began to scream and cramp. As soon as the girl told mamma what she had fed it, mamma poured cream down the babe, and it soon got better. Mamma thinks cream will always help in such cases. She always uses maple syrup or simple syrup for colds. We all love honey very much, but mamma won't allow us to give Huber any. He is my little brother, five months old. He is very smart, but cries much with the earache. Can you tell us of any thing in the next GLEANINGS that would cure it? Papa has lost only one swarm of bees, but it is very cold here yet. We have just commenced making sugar. Mamma sugared off 81 lbs. last Saturday. TESSIE A. TAYLOR, age 10.

Shelby, Oceana Co., Mich., Mar. 29, 1886.

Dear me! when *juvenile* doctors disagree, who shall decide? Some say honey is good for croup, and some say it isn't. I am almost inclined to believe you are pretty nearly right.—Giving children nice rich milk or cream is undoubtedly good for little folks when they have the honey-ache (you know what that is, boys), from an overdose of honey. You remember father Langstroth once told of his little grandchild coming to him and complaining, after eating too much new honey, "O grandpa! I've got 'stomyache'" (honey-ache). His good grandpa at once prescribed milk. This the child took and was better. I often can not eat very much honey myself, without old Dame Nature making a "howl;" but when I take milk with it I get along very well. The old Bible expression, "A land flowing with milk and honey," seems to imply that the two should go together. So, little folks, when you take honey to cure a cold, and then get the "stomyache"—"out of the frying-pan into the fire," drink some good rich milk.—In regard to the earache, I suppose I have suffered from it as much as most people—having had it day and night for a week at a time. Many of the remedies that are commonly prescribed are worse than useless. Never tinker with your ears. Soaking the feet in hot water, and then taking a good sweat, being careful not to take cold, is the only thing which I have found that will give relief. I have instructed the clerks to send you a chromo, as I think you deserve one. ERNEST.

A NIGHT RAMPAGE—BOYS STEALING A SWARM.

Last summer some boys thought they would have some honey (campers, I suppose), so they came about 11 o'clock one night and were carrying off a hive. Just as they were carrying it to lift over the fence, Cousin Will, who was coming home from seeing his "best girl," heard them. They dropped the hive over the fence, upside down. The cover flew off, and the frames fell out, one of which they grabbed and ran over the road, and Will after them. They ran about 40 rods and dropped the frame of honey, and dodged out to the side of the road, and slipped by him before he knew it, as it was very dark, and then he came back and told papa, and he got up and went down with the lantern, but the bees were all out, and he could do nothing with them, and had to leave them thus in the road until morning, then he took out the frames and put them in a new hive and set them back on their stand, and they are now doing well. SKIP.

Covert, Seneca Co., N. Y.

Thank you for your account of the stealing, and the results. Although you say your father could do nothing with the bees, you do not mention whether the bees filled the air in the dark, or only a few flew out, and the rest remained in the hive in the condition it was. If the bees swarmed out in the dark, I should like to know whether they all got back to the hive before daylight. It would be an interesting point to know whether scattered bees can in the dark cluster in one spot, guided only by the hum of their comrades. Can we hear from you again? ERNEST.

DO QUEENS LAY, 3 DAYS FROM THE TIME OF HATCHING?

Pa put up one nucleus in 1885, and got 125 lbs. of surplus honey that season; that was the best yield he ever got from one nucleus. Perhaps you would like to know how he makes a nucleus. He first puts in one rack of honey; second, a rack of sealed brood; third, a rack of fresh eggs; fourth, a rack of sealed brood, so as to leave the rack of eggs in the center, from which he expects to rear his queens; then he lays a piece of ducking over them, and lets it hang down the empty side to keep them warm. Ten queens is the most he ever got from one rack of eggs. He transferred 3 of them before they were hatched, into other nuclei. When they hatched, and were three days old, he found, in each nucleus, a space as large as his hand, with fresh eggs. That was the earliest he ever had them lay, or ever heard of. If you ever heard of any thing like that, let me know.

I have been to school about four years. I like to go to school very much, and I like to see a nice dish of honey on the table.

MARY JANE WALTER, age 11.

Wahoo, Saunders Co., Nebraska, Mar. 12, 1885.

I think Mary Jane, there must be some mistake somewhere, either in your record or in your father's experiments. Did he not by mistake get the old queens from the hive and take them along to form a nucleus? I have done the same thing several times. I do not think it possible for a queen to commence to lay when only three days old, and they must have commenced a little sooner than that, even, or they would not have had a patch of eggs as large as you state.

THE RESURRECTION PLANT.

One day I gave papa ten cents (he was going to Lincoln), and asked him to buy me a hoop or else a flower. He noticed a man at a street corner, who was standing by a little stand with a curious plant to sell. He called it "Mexican moss." Papa bought one for me. It was all dried up, and seemed to have no life in it. I put some water into a teacup, and then put in the plant. It began to slowly open, and soon the cup was too small for it. I then put it in a saucer, and it continued to open, growing green at the same time, until it was nearly as large as the saucer. In about three days I laid it away, and it dried up the same as before. When dried up it is about as large as a hen's egg, and of a light brown color. Once in about two months I take it out, put it in water for about three days, and then put it away. It has a small bunch of thread-like roots, and, when dry, they form about one third the bulk of the whole.

KATIE MELICK, age 11.

Waverly, Neb., March 30, 1886.

Friend Katie, I have seen these resurrection plants, and have been quite curious in regard to them. Are you sure the plant comes to life again? Will it grow and produce more of its kind, if kept constantly wet? I do not believe it will, but may be I am mistaken. May be somebody else can tell us about it.

HONEY, AND OTHER REMEDIES FOR COLDS AND CROUP.

In answer to your question in GLEANINGS, March 15, in regard to honey as a remedy for colds, ma says it is a good one. Sage, steeped and sweetened with honey, is good, and I guess this is the reason California honey, which is gathered from wild-sage flowers, is better than our basswood. I am sorry that Arthur had the croup, for I have had it several times. Take goose-oil or soft lard, add a few drops of spirits of turpentine; with this, bathe the throat and chest, then apply a hot cloth; this gives immediate relief. I am 12 years old, so I do not have croup any more.

There are a good many bee-keepers around here, and I think we shall stand a better chance this year than last, as we all lost heavily—some all. The bees are coming out well this spring. I think snow is a good thing for wintering. Ours were covered completely. When we took away the snow in March the queens we got of Oliver Foster had brood in all stages.

GEORGE W. REAR.

Uxbridge, Ont., Canada.

Thanks, little friend, for the fact in regard to the sage. It is possible that the flavor of the sage in almost all California honey may account for its being better for colds and croup. Mountain-sage honey, from my own experience, does seem to have curative properties that other honey does not have. I should very much like to hear from the other little girls and boys who may have compared sage honey with that from other sources and its effect on colds.—Arthur has now gone home to his parents, but to my knowledge he has not had the croup since he took that "dose of cheese-rinds," and afterward the honey.

You have given us one more fact of interest. You say your bees were completely covered with snow, and that they wintered well. J. B. Mason, in a recent number of GLEANINGS, you remember, thought snow quite detrimental to successful wintering.

ARTHUR HEMPHILL
ELSBERRY MO.
APRIL 1ST.

Our little friend Arthur Hemphill is too small to write his letter, so he has printed it, and sent it to us. We were a little afraid if we simply set the letter up in type that it would lose a great part of its originality, so our engraver has here reproduced it just exactly as Arthur sent it to us. This is what big folks call a fac-simile. What's a fac-simile? Well, ask your mamma, if you don't understand from the above.

ERNEST.

A LITTLE GIRL WHOSE FATHER HAS THREE APIARIES.

My papa has kept bees for eight years. He runs two other yards, one six the other eight miles from our home apiary, where we (that is, mamma and I) work the bees. We gather all our honey on carts, with springs under them, so there is no jar. Pa makes all of our fixtures by water-power, improved for the express purpose. He has invented a bee-feeder, made from a square oyster-can. He thinks it beats them all for cheapness and adaptability. It looks to me like a cigar-box with a sliding cover.

There is, about a mile from us, a spring said to be the largest in Minnesota. We live on this spring branch, in which are speckled trout. Pa caught one weighing 3 lbs. 15 oz.

GRACE KLECKLER, age 13.

Spring Valley, Minn., Jan. 12, 1886.

Very good, Grace; but we should be very glad of a longer letter. Perhaps a great many things that your father does would be interesting to the mass of our readers.

HUBER MILLER.

I have the smartest baby-brother. He is 14 months old. He could walk when he was but 9½ months old; and what do you think his name is? It beats your baby's name a long way. His name is Huber Miller. You know that Doctor Miller is a great bee-man too. My little brother Josie is nearly 6 years old. He was paralyzed when he was 5 years old. He is quite lame in his left leg. He stays in the shop with pa nearly all the time. He makes little boxes, and calls them his bee-hives. We have three white rabbits. Josie and Huber like to play with them. Pa's bees wintered nicely for him. He has 25 colonies. Some bee-keepers lost all their bees this winter. **NANNIE C. SHAUER.**

North River, Virginia, April 2, 1886.

REPORTS ENCOURAGING.

AN A B C SCHOLAR RECEIVES 97 LBS. OF HONEY PER COLONY.

I AM an A B C scholar, and have kept bees for a year now. Last year I worked for extracted honey, and took 97 lbs. per hive. My bees are right in the heart of the city, and I think this was doing pretty well. Not one colony offered to swarm, and I did not increase at all. I wintered them in Simplicity hives, packed with chaff, as you directed in the A B C. They came through the winter very strong—not one colony lost, and all are doing very well now.

SHALL WE DIVIDE OR NOT DIVIDE, IN ORDER TO GET THE MOST HONEY?

This year I decided to work for comb honey, and I should like to ask you if as much *comb* honey can be obtained if we keep the old stock in very strong condition, and give plenty of room for surplus, as if you divide at the beginning of clover yield and have two colonies at work. I have looked this up in all my works on bee culture, and can find no satisfactory answer to it. **PERCY T. WALDEN.**

37 Putnam Ave., Brooklyn, N. Y., Apr. 23, 1886.

Friend W., the question you propound is an unsettled one. See what is said in regard to it on page 271.

WINTERED 108 COLONIES OUT OF 110.

I am much pleased with the new departure in the interests of horticulture. I like this mixing of subjects extremely well, and would not like to see GLEANINGS conducted on any other principles.

I put 110 colonies in cellar, 4 of which I expected to carry out dead in winter. I have 108 "alive and kicking" at this date, very quiet, and apparently in good condition.

We live on the forty-fifth parallel. Last year was a poor honey-season in this part—nothing but basswood honey, although white clover and buckwheat were abundant. We took about 2500 lbs. from 58 colonies, spring count; increased to 110. Blacks gave better returns with me last season than either Italians or Holy Lands; in fact, the latter did nothing but swarm, as I did not get a pound of honey from them, and had to feed them for winter. I am trying some young queens that are crossed; and if they don't do better, off come their heads.

Almonte, Can. **J. K. DARLING.**

TOBACCO COLUMN.

I, THE undersigned, have quit the use of tobacco in all its forms; and if I am entitled to a smoker, please send the same. If I ever commence again, I will pay you for the smoker. **J. L. BAKER.**

Henton, Shelby Co., Ill., Feb. 26, 1883.

I received my smoker, and was well pleased with it; and if I ever use the weed again I will pay you for it. I am very much obliged to you. GLEANINGS comes all right. We put 8 colonies of blacks in the bee-house last fall, and took 8 out. Two were robbed, leaving 6 strong colonies.

Barber's Mills, Ind. **ISAAC THROSSIKILL.**

A LITTLE GIRL'S INTEREST IN HER BROTHER.

Brother John has quit the use of tobacco, and desires me to say that if you see fit to send him a smoker he will pay for it if he ever uses tobacco again. **LAURA M. HOBBS, age 12.**

Middleport, Meigs Co., O., Mar. 22, 1886.

Well done, friend Laura. You now see how much a little girl may do if she sets about it. After your brother sees your letter here in print I am sure he will not want to break the promise he has given here before so many people. You see the promise is down in white and black, and it has been printed more than five thousand times, and perhaps ten thousand people will see it, and he will surely stick to it before the eyes of all this great company. Don't you think he will?

WILL QUIT THIS TIME.

My husband has left off tobacco, and I thank God. If you send him a smoker, I should be glad. He left off two months ago, and I guess he is in earnest this time. I thought so when I married him; but he says he will own up and pay for the smoker if he fails again. He is too proud to own his weakness. I think you will get him this time; because if he did use it he would pay up.

MRS. D. E. CLICKNER.

South Allen, Hillsdale Co., Mich., Mar. 6, 1886.

I agree with you, my good friend, for I think we have got him this time. If he has consented to let you write this letter, to be published, that consent and that promise will brace him up to hold out.

I saw your offer in GLEANINGS, to any one who has quit the use of tobacco. Well, I have induced a man who is living with me, and who has used it for 30 years, to stop. He says that he will never use it again if you will send the smoker. I will stand good for him; and if he resumes the use of tobacco I will pay for the smoker. There is another who has quit chewing. We had a prayer-meeting the last night of the old year, and prayed and sang until the new year, and he set out to quit then, and has gained ten pounds. **M. SIMPSON.**

Gatesville, Coryell Co., Texas, Feb. 27, 1886.

Well done, friend S. And, by the way, I think one of the most efficient modes of working against this tobacco evil is to get your friends to quit, and also get their consent to let you have the promise printed in GLEANINGS. If you stand good for that friend, we shall be safe, and the Master will stand good for us all while we are trying to further the cause of purity and temperance.

OUR HOMES.

Thou shalt not covet thy neighbor's wife, nor his manservant, nor his maidservant, nor his ox, nor his ass, nor any thing that is thy neighbor's.—Ex. 20 : 17.

WHILE I write this beautiful 10th day of May, our country is stirred by fierce conflicts between labor and capital. With the beautiful weather we have had, and the bright prospects for bountiful crops, it would seem as if not only all nature but all mankind should be at peace with themselves and at peace with God. Why must we have such troubles, and this, too, in a land of liberty, and a land of churches and Christian people? Some will tell us it is caused by one thing and some another. But is it not true, that the one great prime cause is the breaking of this last of the commandments? We are continually wanting something that belongs to our neighbors. I have been told that the Chicago troubles were mainly caused by a class of people that would take all the property in the world away from the rich and give it to the poor; that is, that they would have it divided up and equalized. I have not been told whether gamblers and inebriates and highway robbers were to have an equal share with the rest or not; but I suppose they would, of course, come in. The only class that could think of wanting such an arrangement brought about would, of course, be those who expect to gain, and who are dissatisfied with the place in life that God has seen fit to give them. Now, it is not alone the gambler and inebriate and the highwayman who want what belongs to their neighbors, but I am afraid, my friends, the disposition lurks to a greater or less extent in the hearts of all of us. While it is true, that there are multitudes of good people who do not want a copper but what justly belongs to them, and who would not find any happiness in the possession of something for which they had given no fair equivalent, yet for all that these same good people sometimes get mistaken notions about the rights of property. Sometimes one who is employed by a large firm or company gets into a way of fault-finding, something like this:

"Now, just look here; I have been at work for Mr. A, B, and C, and have just been coining money for them, and yet I get only a paltry so much a month. If it were not for me, their business would half go down."

Or, perhaps, A, B, and C may get into a way of speaking of some of the best of their help as follows:

"Just look at that man. What was he when we first took him into our employ? He was not earning, all together, fifty cents a day. We took him in hand and taught him business principles. To make him feel pleasant and contented we advanced his wages time and again, and are now really paying him more than he is worth. But do you suppose he ever thinks of it, or ever feels a spark of gratitude? Not he."

Now, friends, the attitude of the employers is a bad one, and the spirit of the employe is a bad one. On both sides there has been the sin of covetousness, and the only real, true, rational remedy for this sin is the spirit of Christ—a spirit that prompts us to make it our business in life to do good, and to help the world along; the spirit of suffering long and being kind, even to the unthankful; a spirit of not being puffed up; of not thinking of what is our own or our just dues; of not being too hasty to think evil; the spirit that will enable us to bear and believe and hope and endure. I have told you before how this disposition grows on us—a disposition to complain and find fault when not getting our just dues. Do you not see that it is in direct opposition to a spirit of thankfulness? When Miss Ophelia asked Eva where she had rather live, up north or down south, she replied at once, "Down south, by all means." When asked for an explanation she replied, "Because there are so many more to love down south," meaning the negroes. Sometimes we complain because our station in life compels us to wait on so many different people. Reader, are you a waiter? If you are, instead of complaining of your lot, rejoice because you have so many more to love. Do you not think such a spirit would do much to quell the dissatisfaction that has sown the seeds for these present strikes that are stopping our railway trains, stopping the freights in many of our large cities, stopping mills, coal-mines, and factories, because of the disagreement between employer and employes—disagreement where there ought to be thankfulness and warm friendship on both sides? While so many are seeking work, it seems to me the man who furnishes work ought to be regarded as a public benefactor; and while so many are seeking to get faithful helpers, ought not those who pay them their wages week by week and month by month, to feel grateful because they have efficient and faithful helpers? I suspect that all these troubles attendant upon strikes have started in the first place from a habit of gossip in our homes. Perhaps at the family meals we have been discussing imagined wrongs when we ought to have given thanks for undeserved blessings. Before eating our food we ought to give God thanks; and then, to carry out the spirit of asking a blessing, we ought to be, by word and action, giving God thanks while we sit at the table; and thanks to God come pretty near, as you know, to thanks to our fellow-men. "Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me." If you have said "thank you" and *felt* "thank you," to those who have helped you during the day, you have in one sense said "thank you" and felt "thank you" to Christ the Savior. How little chance there would be for strikes and quarrels in our business relations, if this spirit of thankfulness were cultivated and developed!

There is a want of faith between employer and employe—a want of confidence. Each seems to recognize the other as an enemy. Each seems to recognize the other as greedy and avaricious, and working only for the "almighty dollar," and not for love to his fellow-man. There is too much of greed and too much of a want of conscience, I allow; but let us not be discouraged when we see this. Let us look for the better qualities that many times overbalance the evil. Good traits and evil traits may often be found in the same individual; or, if you choose, we often find men who seem to have a lack of principle in one direction, and in the next they show themselves liberal and generous. I don't know why it is, and I have just been thinking perhaps you may see the same disposition in myself. If you do, please think gently when you see my imperfections, and remember my other good qualities in a way that will help to overbalance them. Education, many times, has much to do with it. We have been accustomed to do tricky things, and don't stop to realize how wrong they are; and at the same time we may in general be generous and liberal. Let me relate a little circumstance.

I have just purchased a span of horses that cost me toward $400. Good judges declared I had one of the best teams in the county. For several weeks they seemed perfect, without a flaw or fault. Finally one of them showed unmistakable symptoms of what we took to be blind staggers. A good friend of mine, and one whom I have always considered to be a very honest man, advised me to keep still about it and never mention that such a thing ever happened. This attack happened luckily (so he said) out in the fields, where nobody noticed it.

"Just keep still about it; take him into the city of Cleveland; and as nobody can see *a thing* amiss in his looks, you can sell him for all he cost and more too."

I protested.

"Why, said he, he was put on to you, and you are an innocent party. Just sell him the same way you got him, and may be he won't show it again for months, and perhaps not at all."

I quietly replied, that, if he were sold, the one who bought him should know as much about his failings as I did.

"Why, my friend, you can never get through the world that way. You will be swindled when you buy, and swindled when you sell; for if you tell what you know of this horse, you might not be able to get a fourth of his value."

I replied that I had got through the world so far, and never lacked friends or money, and that I should take the chances of being honest before God in all my transactions, no matter if it did cost me $150 or more.

I mentioned the subject a few evenings ago at one of our teachers' meetings, when an old farmer present said that the fashion of buying and selling stock or produce in the way I had illustrated was the besetting sin that was the ruin of our churches, many of them, as well as of their members, and that strict honesty in deal was more needed than almost any other one thing.

Now, friends, how much do you think such transactions have to do with the want of faith between employer and employes? or the lack of faith among men in each other, because of these crooked things? I am happy to tell you that a veterinary physician told us a few days afterward that my horse hadn't had the blind staggers at all. He said that it was caused by a rush of blood to the head; perhaps by overfeeding, or more likely because the new collar he had been wearing didn't fit right, and obstructed the circulation. He said if the horse had had the blind staggers it would show in the animal's eyes; whereas his eyes looked perfectly bright, and he was as full of life the minute after the transaction as he ever was. Furthermore, he never showed any such symptoms except when he was pulling a load. Now, then, the friend whom I have quoted above was an old farmer and an old horse-trader. A great part of his life had been spent buying horses of the farmers for city markets. I may not have given the conversation exactly as it occurred, but the substance of it was the same. A few days afterward I wanted to buy some manure of this same friend. As he kept a good many hens and only one horse, a large part of the manure was from the poultry. I told him that, under these circumstances, I would give him 25 cts. more for it than what I had paid other people. He said he didn't want any more; he was quite willing to sell it at the regular price, if I would take the whole. I examined it, and told him it was well worth 25 cts. more, but I could not make consent to take it. So you see he is not close in deal, and does not lack in liberality. These things are, as you see, a good deal the force of habit. No doubt Satan takes advantage of these habits and ways; and no doubt he is constantly seeking opportunities to whisper covetous thoughts and feelings to us. I have seen this little evil weed of covetousness take root, and grow. I have seen it increase from month to month, and from year to year. When the poor tempted sinner gives way to it, and indulges in uncharitable thoughts of his friends and neighbors, he soon gets to talking to others about his wrongs and indignities; and if the love of Christ does not come in to pull him out of the abyss into which he has fallen he may not bring up until he reaches the penitentiary or insane-asylum.

A good deal of this spirit of covetousness comes from mistaken notions that people have about what others *ought* to do. A pretty wise old lawyer once said to me, "People *ought* to do whatever they agree to do. When a man does that, he is a pretty good man."

Perhaps this code might not be safe for a Christian, but I think all of us would be better Christians if we kept the matter in mind. A man once brought me half a barrel of maple syrup. Now, I had learned by experience to be careful about buying. I told him I would take it if it was just to my notion, and the price suited. I was careful not to say if it were *good*, because so many had declared that their maple syrup was strictly first class, when I didn't pronounce it so at all. After testing it I told him he must have been careless about cleansing the barrel, for that it had a musty taste that would very much injure the sale of it with my customers. He declared there was no musty taste about it at all. I pleasantly told him we would have to call it a difference of opinion, but that I didn't care to buy it.

At this he became abusive. He said that was just the way we town folks took advantage of farmers. We got them to bring their produce, then pretended there was some fault with it, in order to get it for half its value. Now, I hadn't *agreed* to buy the man's maple syrup at all. I had advertised to buy maple *sugar*, but hadn't advertised to buy *syrup*, and he was abusive because I exercised my privilege of buying or not buying, as I chose.

Suppose I want a man to work for me. He says he will work for two dollars a day, but he doesn't care to go to work at a less price. Now, perhaps I am acquainted with him, and do not consider him worth over *one* dollar a day; but he has a perfect right to refuse to work for less than two dollars, if he chooses. I have no right to feel hard toward him, nor to complain. His strength and skill are his own, and he has a perfect right to do what he pleases with them — that is, within the bounds of reason. He has as good a right to ask two dollars a day for his labor as the man who raised strawberries in February has a right to ask two dollars a quart for them. If we do not want to pay that price for strawberries, we are at perfect liberty to decline, or let them remain in the greenhouse where they were grown. Just the same with labor. Although strawberries could not be raised at the above prices and sold here in Medina, I should have considerable respect for the man who was so much of an expert with plants and fruits that he could raise a crop of berries in the greenhouse every time without fail.

I admire skill in any department, and I do love to see men and women who can command big wages. When I am in need of such skill, it is a great pleasure for me to pay big wages. So far, well and good. But suppose some old hand of mine should make up his mind that he couldn't work for me any longer unless I should pay him considerably more than I had been paying. Ought I to feel hard toward him? Not at all. Nor has he any right to feel hard toward me if I pleasantly say I can not afford to give what he thinks he ought to have. Neither of us should feel hard if, in discussing the matter we can not agree. I may think he magnifies his value, and he may think I am mistaken in thinking I can get along without him, or supply his place easily. We often have different opinions about these things; but if we are striving after righteousness, we certainly ought not to feel unkindly toward each other because of these differences in opinion. Now let us go a step further, and suppose this hand should wait until the busiest season of the year—the time, in fact, when it would be most difficult for me to supply his place on short notice, and then demand an increase of wages before he would consent to keep on with his work. My friends, I think he has a right to do this if he chooses, although it seems to me it is a rather unkind way of doing, especially if relations have been of a friendly nature. If there has, however, been no agreement in regard to giving notice before leaving, I can not see that we should have any right to censure very much. My old lawyer friend would say, "What was the agreement?" If no agreement at all on either side in regard to stopping without notice, he would say we had no right to find fault. Old and tried hands are often hired by the year, and sometimes an agreement is made that either party shall give a notice of 30 or 60 days if they wish to change relationship. A Christian man, or even a gentleman, would usually tell his employer that he would stay by him until he got over his crowd, or until he could look up a substitute. Those who are working for me have almost invariably been willing, or preferred to do this. Perhaps it is because those who do the work for me are, as a rule, personal friends, and I am glad to say those who are not given to the sin of covetousness. They do not want to put me to trouble and expense, even though they may think I have not paid them as much as I might have done. A Christian man is commanded to "do good to those who hate" him. Now, if we are to consider the interests of our *enemies*, and try to do them good, how much more are we under obligations to consider the interests of those who have been our *friends*, and strive to do *them* good!

Now, when we consider a case where the entire hands of an establishment, or at least a great part of them, enter into a combination to demand more pay, we come right into the strike business. Is it right? Well, I think it is right and proper for laboring people, or working people of a factory, to agree together in this way, if they choose so to do. But if they are Christians I think they will give their employer sufficient notice beforehand, so that he may make arrangements to avoid loss. Everybody has a right to work or not, as he chooses. He has a right, too, to sell his skill and strength to the highest bidder, providing he does it in a gentlemanly way—in a way consistent with "thou shalt love thy neighbor as thyself." Well, now, very likely I look at the matter from one side; but it does not seem to me as if it were right for those who give up their places, to discourage in any way or in any way try to prevent new hands from taking the places they vacated. When we step over into this matter, telling others what they shall or shall not do with their labor, it seems to me we are getting on dangerous ground. I have sometimes replied to the friends who had their hives and honey stolen, that there was a fault away back somewhere, and that the best remedy would be to encourage Sunday-schools and churches in places where such things happen.

It seems to me that such is the case where this matter of boycotting and strikes is rampant. There surely is a lack of godliness, a lack of Bibles, and a lack of Christian spirit. I can hardly think such a state of affairs can come about where the proprietors are good Christian men—where they have been working for the interests and for the salvation of the souls of those they employ. It seems to me that it indicates a bad state of affairs, and that this bad state must have existed some time back, or matters would never have come to such a crisis. We have proof of this from the fact that the law is almost powerless. These combinations are formed, and this work of intimidating any who attempt supplying the place of the strikers goes on in broad open daylight, and in a land that we fondly call a land of liberty. In our neighboring town of Akron, strikers have even intimidated the proprietors of boarding-houses, threatening them if they entertained those who propose to take the places of the strikers. Jesus said, "Blessed are the meek, for they shall inherit the earth." Strikers seem to think that the right and proper way to inherit the earth is to do it by scaring the people with bowie-knives and revolvers; and these things go on, and nothing much is done about it. Well, I am not sure that much can be done about it, unless we begin at the root of the matter.

When a man tells me that he can not get along with his wife because she has got to be so ugly, I usually inquire if there is not a *pair* of them that have got to be "ugly." And where a manufacturer has strikes among those in his employ, it seems to me that it indicates not only a bad spirit among his hands, but a bad spirit in the employer. A short time ago I went with my daughter Maud to visit one of her college mates. This college mate had just begun housekeeping, and the young couple were a model husband and wife. After a while the husband incidentally remarked that they had had their wages cut down. I asked him how the employers managed to do it. His reply was, "They did not manage at all." They had been working all the week just as usual, and supposed they were to receive their usual wages. Saturday night, instead of receiving the usual amount, they found that about 20 per cent had been kept back. Some of the most intelligent of the men went back and asked if it would be out of place to ask for an explanation, telling the paymaster that, if business was dull, and the cut-down was a necessity, they were not disposed to be unreasonable, but felt as though something ought to be given by way of explanation. The paymaster replied in a harsh, overbearing way, "If you don't like the pay we give you, you know what to do." These same proprietors have had terrible troubles within the past few weeks; and if I should treat my hands in that way, I should be sure that terrible troubles would come here. Why, I wouldn't hurt their feelings, as I know such a thing must hurt, for all the money the world could furnish. I have sometimes had to cut down wages; but I have never done it, I believe, without talking the matter over, and arranging for it in a neighborly and friendly way a week or more *before* the reduction was to commence. Sometimes my hands go away because I can not pay them more, but almost always with a friendly hand-shaking, and kind words on both sides. Dear reader, is it not worth something to so live that your relations with your fellow-men may be like this? and is there any name given under heaven whereby we may be saved from these troubles except that of Jesus Christ?

This very matter, by its strong contrast, gives us a wonderful glimpse of the beauty of the character of Christ. He came among men, a man himself, and yet a man that coveted nothing belonging to his friends and neighbors; a man who, although he was intensely human, yet labored and died for others, and never performed even one miracle for himself — no, not even when he hungered and thirsted. Thank God, the spirit of Christ exists in other human hearts, even at this date. Multitudes of earnest, honest Christians are laboring for the good of their fellow-men, scarcely thinking or caring for self; and through such as these, such as are living examples of the Christian spirit, we are to find relief from all these troubles. So long as great multitudes are living for nothing but money or gain, so long shall we have fierce conflicts; but when men can be educated and taught to obey in spirit as well as action the commandment at the head of this, then may we expect "thy kingdom come, thy will be done on earth as it is in heaven."

A FRIEND IN TROUBLE.

AND SAID TROUBLE CONTAINS A VALUABLE FACT FOR THE ENCOURAGEMENT OF BEE-KEEPERS.

I WROTE to ask the editor of the Baltimore Weekly *Sun* if he could tell me how to get rid of honey-bees from our house. He replied that he would advise me to write to A. I. Root, Medina, Ohio, "who is authority on all such subjects." The bees took possession of the side of the house, between the plastering and weather-boarding, and have been there for 15 years and more. Twice we had them removed, with the promise they would not return; but the next season they came with double quantity. A year ago the moths destroyed them; but in May, *three* large swarms came in, and are still in possession. The house is suffering for need of repairs, and I am in great distress, as I can't get any one to go near them, as they seem to be very spiteful. Is there any way to keep them off, or to destroy them? I shall be truly grateful for any thing you can tell me to do. I am a poor woman, with no gentleman to act for me. C. T. FENWICK.

West River, Md., April 10, 1886.

Why, my dear friend, your little story contains something wonderful for the encouragement of bee-keepers. If you can not find some enterprising bee-man to help you out of your trouble, it will be strange. We have for years been working and devising to get some arrangement that would induce bees to take up, of their own accord, with some hive already prepared for them, instead of going to the woods. Now, your house, or, at least, that portion of your house, seems to have, by accident, met the requirements entirely; that is, if, as you say, bees persist in coming to you for a lodging-place. Are you not mistaken in thinking that *three large swarms* came all at once? If so, it is a phenomenon beyond any thing heretofore recorded in this line. If you don't hear from somebody who will help you out of your difficulty within ten days after the issue of this paper, let us know, and I think we can help you. We are very much obliged indeed to the editor of the Baltimore Weekly *Sun* for his good opinion of us.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

SOME weeks ago our good friend Chalon Fowls, of Oberlin, O., wrote us that he had been talking with one of the largest wholesale firms, dealers in fruits and vegetables, in Cleveland, in regard to bogus comb honey, but that he could do nothing with them at all. They just laughed at him when he attempted to convince them that there was no such thing as manufactured comb honey in the markets. In despair he wrote to me, asking me to write to them, as they were personal friends of mine. I did so, and here is their reply:

> We received your bee-journals, and read all the articles you marked on the subject; and until the other side bring forward some proof to substantiate their claims, we shall not admit that there is such a thing as manufactured comb honey.
>
> C. CHANDLER'S SONS.
>
> Cleveland, Ohio, April 19, 1886.

You see, friends, the victory is ours. Through the influence of the bee-journals, and the friends of the honey-bees, these fraudulent statements have been met and refuted; and almost every live intelligent paper has given notice to its readers that the whole thing was a mistake. It is encouraging to find that we are not helpless in such matters; that earnest, persistent, faithful effort will always carry the day, especially in defense of the truth. Another thing encouraging in regard to the matter is, that we have proved that the press at large is not unwilling to refute error when it is rightly managed, with good men's names to back it. The N. Y. Weekly *Witness* held out hard and strong to the adulteration stories; but when I sent them a letter, explaining fully the points they had misapprehended, it was published at once.

NOTES AND QUERIES.

HURRAH FOR THE ALLEY DRONE-TRAP!

YOU will remember I got a lot of drone-traps of you, and I thought it might be of interest to you to know how they work, so here goes. I find the Alley drone-trap a perfect blessing, as you will never have a swarm to abscond, and you need not clip your queens either; and for second swarms, where there are more queens than one you can trap them and pick the nicest one; or if you need a virgin queen for a queenless colony, use the extra ones, or do as you please with them. I say, "Hurrah for Alley's drone-trap!" I would not be without mine for twice what they cost.

Gonzales, Tex., May 3, 1886. M. BROERS.

25 CHICKENS HATCHED OUT OF 26 EGGS.

You had such *good* luck raising chickens this spring, I thought I would tell you of mine. I set 26 eggs, and had 25 chickens. They are all alive, and doing well. MRS. T. H. MILES.

New Richmond, Pa.

ANOTHER USE OF THE CLARK SMOKER.

I got one of your smokers—not for bees, but for bugs. I have tried it with tobacco-stems, on rose-bushes, etc., and it performs beautifully. I have not seen it spoken of as a "terror to evil-doers" in that way, and I thought you might be interested in hearing of its success. W. B. MARSHALL.

Indiana, Pa., May 5, 1886.

A GOOD REPORT FOR AN IMPORTED QUEEN.

You wish to know every one's experience with imported Italian queens. Mine has been good. The imported queen that I got from you a year ago last July is far ahead of any other I have ever had, in every way. Her bees are quieter in winter, and will not swarm till every crevice in their hive is filled up. I have sold off most of my other stocks, and will keep only those raised from my imported queen. THOMAS CHRISTIAN.

Lorraine, Ont., Can.

HOW TO USE THE HEDDON SLATTED HONEY-BOARD ON THE SIMPLICITY HIVE.

White clover is unusually plentiful this spring. I should like to ask how you use the Heddon slatted honey-board on the ordinary Simplicity hive. By answering the above you may oblige others as well as myself. I would not think of keeping bees without the A B C and GLEANINGS.

FRANK A. DURAND.

Esdaile, Wis., April 29, 1886.

[We have never used the Heddon slatted honey-board on any hive, but we have made a good many of them to order, made so as to lie perfectly flat on top of the Simplicity frames. The upper stories are then raised enough to make sufficient space for the honey-board, by tacking strips on the upper hive.]

ADVANTAGES OF EXTRACTING.

Two months ago I shipped to Portland some of the whitest extracted honey I ever saw. It was taken from goldenrod and blue aster, and such good clear honey, free of that strong taste, I never had before. The more I see of extracting, the better I like it, for we can keep colonies so much stronger that we shall get honey, even in a poor season. I am satisfied that we can keep down the swarming fever better by extracting before much honey is sealed over, because it keeps the bees working to fill those empty combs. I have no fear about evaporation; warm weather does that all right; and besides, new honey works much easier. Considerable is said about half-pound boxes. Now, why not just cut the 1⅞ box in two, so as to be only half as large around? Then two will take the place of one, and there will be no confusion, you see. I shall try it if nothing prevents. It is quite inconvenient to have a number of different sizes; but with this there would be no trouble. E. P. CHURCHILL.

Lewiston, Maine.

THE SPRING DELIGHTFUL.

We are having a delightful spring. The fruit-trees in this part of the country are loaded with blossoms; the bees are busily engaged in securing supplies from the open flowers, and building up rapidly for the coming season. Our bees, 20 stands, came through all right, bright and clean, the past winter. I am of the opinion that good honey to winter on has more to do with successful wintering than any thing else. We have the Italian bees in A. I. Root's chaff hives, wintered on the summer stands. I have found out that section combs that were not capped over, the honey being removed, are not suitable to use again. They become tough and hard; last season the honey-flow was short. The bees gathered enough to winter well in this part of the country. J. M. MCREYNOLDS.

Topeka, Ill., April 27, 1886.

A GOOD REPORT FROM THE CONTROLLABLE HIVE.

Friend Root:—I have 18 hives of bees in Mrs. Cotton's Controllable hive, and they keep me busy. It is the best hive I have seen so far. I hived one swarm of bees in a Controllable hive last year, June 5, and have used Mrs. Cotton's new system of bee management, and that swarm left me 204 lbs. of surplus comb honey, and came out all right this spring. WM. HIESTANDS.

Palm Station, Pa., Apr. 27, 1886.

[Friend H., we are very glad indeed to hear this, and I have no doubt but that the Controllable hive, managed according to Mrs. Cotton's instructions, will give excellent results. Neither is there any doubt but that Mrs. C. might do a large and profitable business if she would sell her goods at prices something near the usual price asked for bee-supplies.]

OUR OWN APIARY.

EXPERIMENTS WITH PERFORATED ZINC.

SOME one, whom I do not now remember, wrote us that the perforations in our new zinc were wider than those of the foreign make, and that he thought, in consequence, queens would get through. It is to be remembered, that six or eight months ago Mr. Henry Alley, who has had a large experience in zinc, pronounced the foreign as the best. If, indeed, the perforations in our zinc were wider than those of the foreign make, then our perforated honey-boards might be almost of no value for the purpose of excluding queens from the surplus-department. To test the truth of the matter I have made some careful measurements of the perforations, both in our own and in other makes. The instruments used for the purpose were some I had in college for laying out plats and making other accurate drawings. They are capable of measuring down to the four-hundredth of an inch, and with these I obtained the following results:

The width of the perforations in the foreign zinc was nineteen-hundredths of an inch; the width of the American, with oval holes, sixteen-hundredths; the Jones, eighteen-hundredths; our own, a width between the foreign and the Jones zinc. I verified these results with a steel rule having hundredths of an inch marked off, so that I do not think I am far from the correct measurements. It is to be observed from the foregoing, that the perforations in our zinc, instead of being *wider* are *narrower* by a difference that is very slight. If queens can not get through the foreign zinc, then I do not think they will get through ours; that is, if measurements mean any thing.

Now, laying aside measurements with which we obtained the preceding fractions, let us put the zinc to an infallible test; namely, a trial in the apiary. Queens from different parts of the apiary were seleted at random. Each of these was caged over the zinc in such a manner that the only means of escape back to the bees was through the perforations in the zinc. It was amusing to watch them in their efforts to get through. After repeated twisting and squirming, their attempts were of no avail. Finally the apiarist selected the smallest, poorest queen he could find in an apiary of over 300 colonies. The efforts of this queen likewise proved a failure. The apiarist then picked queens up by the wings, and tried to force them through, but found that he could not do so without injuring them. The thorax of a queen is much larger than most people think; and one is apt to suppose, on looking at zinc, that queens can pass through that easily, when an actual test would prove to the contrary.

If a queen can not get through, can workers filled with honey? To answer this question I instructed the apiarist to get two bread-pan feeders. These he was to fill about half with honey, and to put over each the ordinary cheese cloths. The feeders were then placed under the maples some little distance from the apiary. Over one of the feeders as thus prepared was placed a piece of our perforated zinc, so adjusted that the bees could not get at the honey except by passing through the perforations. Over the other feeder in like manner was placed a piece of American zinc. My reason for testing the latter was to see how they compared in results. Besides, several of the bee-keepers have called for this American zinc, stating that they thought it better than the zinc of larger perforations. Well, what do results say? In a short time the bees were swarming over both feeders. Through our zinc the bees seemed to have no difficulty in passing, and, even gorged with honey, they appeared to get out as easily as they entered. Not so with the American zinc. The bees passed through tolerably well; but on becoming gorged with honey they were caged, and could not get out again. At the time I was there, perhaps half a pint of bees were shut in, and unable to make their escape. They could get perhaps half way through, and a few managed to squeeze out, but I am sure the friends will not find it economy to use it.

The size of the perforations should be such as to admit worker-bees filled with honey to pass freely, but not allow the same privilege to queens. As our dies were made after the foreign zinc, it seems to me we have hit the size pretty nearly.

CARNIOLAN BEES.

During the early part of this spring these bees seemed to be crossed with Italians, as nearly half of the bees were of the latter race. Now that the old Italians in the colony have all died off, leaving none but this new race, the steel-gray color mingled with the jet black stands out clearly. One can hardly form a correct idea unless he views a whole swarm of them at a time. But even yet I think when we come to talk about *pretty* bees the old Italians still take the lead. Aside from color, I have not yet discovered that the Carniolans differ very much from the Italians. If the former should in no way prove superior, the mere matter of color or beauty ought not to warrant us in introducing this new race in our apiaries very largely. The crosses with the yellow bees would not very easily be distinguished from the old-fashioned hybrids—at least, customers would not know the difference, even if *we* did.

NUMBER OF COLONIES UP TO DATE.

In addition to the original 181 colonies, we purchased 41 of friends Shook and Rice. After dividing up a good share of the strong colonies we now have 300 fair stocks. E. R. ROOT.

GLEANINGS IN BEE CULTURE.
Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, MAY 15, 1886.

There is none other name under heaven given among men, whereby we must be saved.—ACTS 4: 12.

THE CHAPMAN HONEY-PLANT.

FIFTY plants, strong and healthy, are all growing, as reported on page 391. They very much resemble thistles. We have given them good rich ground, between rows of small apple-trees, so they can remain in the same place three years or more. As soon as they are in bloom we will watch them carefully, and probably have engravings made of the plant in bloom.

A COURSE IN ENTOMOLOGY.

At Cornell, a summer course in entomology and general invertebrate zoology will be instituted under the personal supervision of Prof. J. H. Comstock, of whom mention has been made before. Here is a chance for "beeists" and others who may desire instruction in the special anatomy of the bee, as well as of other insects. Further information can be obtained by writing to the professer in charge.

"A YEAR AMONG THE BEES."

THIS is the title of the book just out, written by our old friend Dr. C. C. Miller. It arrived too late for a review of it to appear in this issue. If it is all as good as the introduction, which we have read, it surely will be a treat to peruse its pages. A glance at the contents is sufficient evidence to show that no practical bee-keeper can afford to do without it. It is published by T. G. Newman & Son, and can be purchased of them for 75 cts , postpaid, or can be obtained at this office at that price.

AN OLD ALMANAC.

W. LINCH, Maysville, Ky., sends us an old almanac, dated 1839. Among other industries mentioned in it we find a short article on the care and management of bees. The writer of said article discourages the cruel use of brimstone, current at that time. The hive he describes is a plain box, 13 inches square. Across the top of this are slats from which I presume combs are to hang. The boxes just mentioned are to be tiered one above the other, according to the strength of the swarm, and in this way the writer says he has tiered them four high. Tiering up, he claims, will largely prevent second swarms, which he asserts are almost useless. The contents of the article shows that we of to-day are not so original in many things as we think.

BUYING NUCLEI IN THE FALL, TO BUILD UP BY FEEDING, INSTEAD OF BUYING FULL COLONIES IN THE SPRING.

ON page 549 of our issue for Aug. 15, 1885, I wrote an article in regard to building up nuclei by fall feeding. If convenient, it may pay you to turn back and read the above article. A friend wanted six colonies of bees to begin with in the spring. Such colonies as he wanted, we told him would cost him over $100 in April, 1886; but we sold him select tested queens and nuclei for a little over $25.00. He was to buy sugar, and feed them up before cold weather came on. Well, now, although our customer was a comparatively new hand at the business, having only his A B C book, and such instruction as, we briefly gave him, I am glad to be able to note that the six nuclei are now six strong colonies — no loss and no dwindling. The question I asked, when the above-mentioned article was written, was this: Will a pound of bees and a frame of brood and a queen, started, say, in the middle of August, build up so as to make what may be called a fair colony by the middle of November? Our friend's experiment answers it in the affirmative. His address is Thomas Painter, Oberlin, O., should you wish to ask him more about it. Besides the saving in money, he has obtained an experience that is worth more to him, perhaps, than the money saved.

MAKING PERSONAL ORDERS.

MANY of the friends within a hundred miles or so of our place have thought it a great advantage to come here and make their orders personally. It is true you can look at the goods and at the same time obtain matters of information. There is this about it, however: There is always a chance for mistake in taking down orders verbally. Then the controversy arises, "Who was at fault?" Only last week there was some misunderstanding in an order made verbally, and the result was that 1500 odd-sized frames were made wrong. If we have it all in black and white, as is in the majority of cases where orders are made by letter, it is a very easy matter to trace the source of the mistake. Another thing, it generally takes one of our valuable clerks sometimes half a day to wait on a personal customer, when the whole transaction by letter could be disposed of in 15 or 20 minutes at the outside. Again, this personal customer, in many cases, wants his goods right away, when the probabilities are that we have written orders with cash inclosed that have been waiting patiently their time. Now, friends, as far as convenient will you not make your orders by letter? and as far as the inspecting of goods is concerned, you are most of you familiar with the wares we handle. If you do not know present prices of goods, write us with a list of what you want, and we will send you an estimate by return mail, with discounts, if any. You see, friends, it is a saving all around. It saves you car fare, it saves our time, and, consequently, is the greatest good to the greatest number by having more orders filled. Not only this, it avoids mistakes and controversies. It is fairness to friends at a distance; and will you not try to accommodate us? Of course, friends who live within 5 or 10 miles of us can save freight by driving out after the goods, and the foregoing does not apply to them.

The above was written by Ernest, to which I add, we do not, by any means, intend to be rough on our visitors. Sometimes we have genial friends who come to see us, who request permission to look around, without bothering anybody, and we are always glad to see such—the more the merrier; but if you come during the busy month just before swarming time, please don't feel hard if you have to wait on yourself a good deal. In regard to personal orders, I would suggest that the party making the order be afterward required to read the copy, and then say whether it is correct.

REDUCTION ON BEES AND QUEENS.

Owing to the very favorable season, we are pleased to state that we are now ready to fill orders for any thing in the line of bees, queens, or full colonies, at June prices.

BUSINESS AT THIS DATE, MAY 15.

Although our trade has been as large as it ever was before, we are filling orders, with but few exceptions, quite promptly. Strikes have made us trouble in some lines of goods by the stoppage of freight. But few if any of our orders are more than a week old.

THE WESTERN PLOWMAN AND TOBACCO.

We are pleased to note that the editor of the *Western Plowman*, of Moline, Ill., has fallen into line, and is going to send his paper free one year, to tobacco-users who give up the weed in every form for a period of one year. The name is to be printed, attached to the pledge given in the first number of the *Plowman;* and if the signer "goes back" on his pledge he is to pay 50 cts. for the paper — that is all. The bright feature of this is, that the man who promises to quit, publishes said promise in black and white; and who would go back on his signed contract, published in a paper, for a paltry 50 cts.?

THE BEE-KEEPER'S LAWN-MOWER.

Those lawn-mowers have exceeded our expectations. Around home the lawn had been neglected, and the grass had grown to a height of six and seven inches, and was of a heavy growth. But one of those little mowers cut it all down. In a few places the grass was eight and nine inches high, but the mower leveled down even this; however, when grass reaches this height it requires considerable strength to run the machine, and to make the job complete the ground must be gone over again. Our boys have experimented with several different mowers, but never found one that, for ease of running and good work, would anywhere near compare with this. For prices see advertising columns of this issue.

ORDERS FOR ODD-SIZED GOODS, CONSIDERED ONCE MORE.

We always try hard to do "all we agree to do," and the regular-sized goods in our price list we at least indirectly, if not directly, agree to keep on hand in readiness for shipment. Now with the crowd on our factory, it is, without question, our duty to fill orders for regular goods first; and orders for odd-sized stuff, that we do not advertise, and do not agree to furnish, must come afterward. This is but justice in several ways. We can generally fill half a dozen orders for regular goods, where the machinery is all fixed, where we could fill only one or two that required delays for a new arrangement, to make something special to order. In making your orders, please keep this in mind: The things we advertise can usually go at once, or pretty nearly so; but things that have to be made specially for you must await their turn.

REASONS FOR BEING THANKFUL.

The weather thus far has been most beautiful. At the present writing, May 12, we have had no frost to do any damage, since the early part of April. During April a spell of beautiful warm dry weather, just exactly as farmers wanted it to get ahead with their work, continued so long that some, who might be in a little hurry to complain, just began to talk about the drought. Since then, beautiful summer showers have blessed us just about as fast as they were wanted; and any one who works outdoors (or indoors either, for that matter) and has not felt a spark of gratitude welling up from his heart, must be, it seems to me, a little hard to please.

KIND WORDS FROM OUR CUSTOMERS.

THE PRINTING AND BINDING OF THE A B C.

I must compliment you on the present edition of your A B C of Bee Culture. The fine grade of ink used, together with the quality of the paper, "bring out" the engravings and type with a wonderful clearness and distinctness. It is a sample of work that would be a credit to any printing and book-binding establishment. J. B. Whitlock.

Eufaula, Ala., May 4, 1886.

NONE MORE WELCOME THAN GLEANINGS.

I wish to say something in favor of Gleanings. I take several journals of another kind, but none are more welcome to my table than bright and happy Gleanings, with "What to Do and How to Be Happy while Doing It." I was very tired when I took your issue for Jan. 15th, but after reading it half an hour I felt like a new man. Wishing you unbounded success I remain resp'y yours,

Brockway, Mich. W. H. Gowan, M. D.

GLEANINGS "A LAMP TO THE FEET OF THE YOUNG."

My children inquire of me every day, "When are you going to get Gleanings? We can't do without it; do get it again." In fact, I have felt as if I were getting a little lonesome too, for we all have a desire to see it first among our other papers. It is a safe journal for a family to read, and a lamp to the feet of young and old. Would that the children would read Gleanings, and practice its teachings, in place of reading novels and attending dances and such like. O. P. Wright.

Millerstown, Perry Co., Pa., Apr. 26, 1886.

GOOD GOODS AT A LOW PRICE.

My goods, which were shipped March 5, have arrived. They were delayed a long time on account of the great strike. One of the ends of the barrel was out except one small piece. Nothing had lost out. The railroad men must have been very careful not to lose any thing out of the barrel. Those culled sections are much better than I expected. They are good enough for me. Every thing you sent is cheap. Those ten-cent screw-drivers are the cheapest goods I ever saw. You must buy cheap, or you could not sell so cheap; but how can manufacturers make a living at such low figures?

G. W. Beard.

Milano, Milam Co., Tex., April 29, 1886.

TROUBLE TEACHES US HOW TO SYMPATHIZE WITH EACH OTHER.

I received my second lot of goods all right. I think those ½-lb. tumblers are "boss." Every article was found just as ordered. I am well pleased with every thing. I made quite a lot of hives and sections this spring for myself and neighbors. Bees are doing very well at present. They commenced on fruit-blossom this morning. Friend R., will you send me a lot of sample copies of Gleanings, especially of Mar. 15? You ask why that date. This is a Christianlike neighborhood, and a great many of them are keeping bees, and I thought to present some of them with a copy, and perhaps by the operation I might receive some subscriptions for the same. The one particular feature about that issue is in Our Homes. I have lost considerable stock this winter, and from causes for which I can not account, nor can any one else whom I have seen. I have worried over it considerably; but when I read Our Homes, I took to quite a different notion, and have quit worrying and troubling myself about things which I can not help. I hear some of my neighbors are losing in the same way, and perhaps those numbers will help them. It has helped me wonderfully. S. B. Miller.

Amish, Iowa, Apr. 23, 1886.

WHAT OUR OLD FRIEND W. H. SHIRLEY THINKS OF US.

It is a keen pleasure to deal with you, and I wish there were a great many more like you.
Millgrove, Mich., Mar. 30. W. H. SHIRLEY.

PERFECT SATISFACTION.

The goods I ordered of you have given perfect satisfaction, and I have concluded that when we need any thing in your line to send to you for it.
Pattonville, Texas. J. M. CROCKETT.

I believe that all bee-men claim "kin," and, besides, I have gotten it in my head that you are a real good Methodist, and that we are brothers.
P. H. MARBURY.
Hearn, Clark Co., Ark., April 9, 1886.

I am well pleased with GLEANINGS, especially the Home Papers, and its high moral tone. As for the mix, "variety is the spice of life."
DANIEL E. ROBBINS.
Payson, Adams Co., Ill., Dec. 28, 1885.

I received the goods all right, and was very much pleased with them. I think that the A B C book is just splendid, as it is gotten up in such nice style. Your $7.00 saw-mandrel is a beauty. The freight on goods was reasonable. H. H. FISH.
Spencer, Iowa.

PUTTING THINGS UP SO NICELY.

The goods have come to hand all right. You make me feel glad when I see your efforts to please by putting things up so nicely, and discounting whenever your margin will bear it, even in the smallest things. GEORGE BOON.
Thorp's Spring, Hood Co., Tex., May 2, 1886.

THE ADVANTAGE OF THE HUMBUG AND SWINDLE DEPARTMENT.

The maple syrup was received a few days ago. We are well pleased with it. Your exposure of the blueberry-plant fraud has saved me considerable money, as I had sent for a price list, and had intended to send for some plants. S. M. MOHLER.
Covington, Miami Co., O., Apr. 13, 1886.

THAT IMPORTED QUEEN.

The imported queen is here and in good condition; out of the ½ lb. of bees that accompanied her, only about 25 were dead, although they were three days on the way. In less than two hours after they were hived, the queen commenced to lay. Thanks for your careful packing. THOS. & BENJ. YOUNG.
LaSalle, Ill., Apr. 26, 1886.

SEEK YE FIRST THE KINGDOM OF GOD, ETC.

The knowledge you impart in bee culture is good, but it is secondary to that other good quality you display in your writing in bee culture, in preaching the gospel. I ascribe your exquisite flavor of apples and honey not altogether to fresh air, but in a great measure to the truth of the Spirit. See Gal. 5:22. May the God of peace sanctify you wholly, and preserve you until the coming of Christ. With Christ in the heart the world is already a paradise.
East Camp, N. Y., Dec. 19, 1885. PHILIP WECK.

THAT A B C BOOK.

I am just in receipt of your beautiful book, and can only say that my astonishment surpasses any thing I could express, and I can only say that you not only have my warmest thanks, but you may rest assured that, if I can do any thing in the matter at all I shall look to you as the source from which I shall look for all my gettings. I shall read it up carefully, and report. H. W. NEAL.
Wellsville, York Co., Pa.

HOW A BEGINNER SUCCEEDS AS PER INSTRUCTIONS IN THE A B C OF BEE CULTURE.

I have been a student of yours through your A B C book. I purchased one of Rev. Edwin Dudder, and, at the same time, one stand of Italian bees, two years ago this month. I have transferred, divided, and united weak swarms, hatched queens in the lamp-nursery, and introduced them to queenless swarms successfully. Your book has enabled me to do this work, and it has been a great pleasure to me, as well as a source of profit. I wish to express my thanks for the pains you have taken to make bee culture a success for those having no experience. I use one style of hive—Langstroth improved, making them myself, and buying the broad and narrow frames, section boxes, and foundation, etc., of King & Aspinwall. As I look over your book and study it I have a growing desire to speak to you through the pen. C. M. HOWELL.
Andover, N. J., March 9, 1885.

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

SECOND QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED.

This wire cloth is second quality. It will answer nicely for covering doors and windows, to keep out flies; for covering bee-hives and cages for shipping bees; making sieves for sifting seeds, etc.

Inches Wide.	No. of Rolls.	Number of Square Feet contained in each Roll Respectively.
26	71	22 rolls of 217, 37 of 216, 1 of 195, 2 of 215, 1 of 210 s. f.
28	11	5 rolls of 233, and 2 of 234, s. f.
34	7	3 rolls of 281 s. f.
38	37	26 rolls of 316, 2 of 317, 1 each of 632, and 285 s. f.
42	1	1 roll of 245 s. f.
44	2	1 roll of 366, 1 of 348 s. f.
48	2	2 rolls of 400 s. f.

FIRST QUALITY WIRE CLOTH AT 1¾ CTS. PER SQUARE FT.

The following is first quality, and is worth 1¾ cts. per square foot. It can be used for any purpose for which wire cloth is ordinarily used; and even at 1¾ cts. per sq. ft. it is far below the prices usually charged at hardware and furnishing stores, as you will ascertain by making inquiry. We were able to secure this very low price by buying a quantity of over one thousand dollars' worth.

Inches Wide.	
22	1 roll 143 s. f.
24	42 rolls of 200 sq. ft. each.
26	56 rolls of 216 sq. ft. each; 1 each of 199, 195, 201, 200, 227, 204 sq. ft.
28	72 rolls of 233, 11 of 224, 8 of 222, sq. ft.; 1 each of 257, 219, sq. ft.
30	36 rolls of 250 sq. ft.; 1 each of 235, 275, 240, 125, 237 square ft.
32	13 of 266, 7 of 256, 2 of 253 sq. ft.; 1 each of 250, 275 sq. ft.
34	30 rolls of 283 sq. ft. each.
36	22 rolls of 300 sq. ft. each; 1 each of 288, 279, and 285 square ft.
38	1 roll each of 300 and 316 sq. ft.
40	1 roll of 233 square feet.
42	1 roll of 350 square feet.
46	1 roll of 192 square feet.

A. I. ROOT, Medina, Ohio.

JOB LOT OF POULTRY-NETTING,

At 1 ct. per sq. foot; 5 per cent off for two or more pieces; 10 per cent off for 10 or more pieces; 1½ cts. per sq. ft. when we have to cut it. Besides this job lot we keep in stock the regular 4-foot poultry-netting, in rolls of 150 lineal feet at same price as above. These figures give the number of sq. feet for each roll; and by dividing by the number of feet wide you can determine the length of each piece.

In. wide.	
60	1 piece each of 170 sq. ft.
72	1 " " " 66, 72, 72, 150, and 186 sq. ft.

A. I. ROOT, MEDINA, OHIO.

CONVENTION NOTICES.

The 5th regular meeting of the Hill Co. Bee-Keepers' Association will be held on the first Tuesday in July, at the apiary of Hon. J. M. McDaniel, Peoria, Tex. At same time and place will be held a bee-keepers' honey-picnic. H. A. GOODRICH, Sec'y.

CIRCULARS RECEIVED.

The following have sent us their price lists:

D. A. Jones Co., Ld., Beeton, Ont., Can., a 16-page price list of bee-supplies in general. We are glad to note the progress of our Canadian friends, as evidenced by their new list.

C. M. Hicks, Fairview, Md., a 4-page list of apiarian supplies.

N. E. Cottrell, Burdick, Ind, an advertising sheet—specialty, Syrio-Italian queens.

J. P. Moore, Morgan, Ky., a 4-page circular, bees and queens.

Tygard Sons, 2119 Jane St., Pittsburgh, Pa., a 4-page list—specialty, square glass honey-jars.

I am being asked my opinion of the new circulars Mrs. Cotton is again sending out quite plentifully. The statements she makes, and the prices she charges for the goods she sends out, would, in my opinion, forbid her being classed with our regular supply-dealers, to say nothing of the strings of complaints against her that have filled our bee-journals for years past.

REDUCTION IN PRICES.

We hereby notify our customers that there is a reduction in foundation from the prices quoted in our *March* retail price list. All parties interested will please mail us a card for new prices.

CHAS. DADANT & SON,
11d **Hamilton, Hancock Co., Ill.**

HORN PAYS EXPRESS CHARGES SEE ADVERTISEMENT.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have fifteen or twenty prolific black queens; 25 cts. each (with cash accompanying the order) takes them.
CHAS. H. SMITH,
P. O. Box 908. Pittsfield, Mass.

FOR SALE.—25 black queens, ready May 20th, until July 10th, at 25 cts. each, or five for $1.00.
ROBERT MITCHELL, Washougal, Clarke Co., W. T.

FOR SALE.—3 black queens at 25 cts. each, and 9 hybrid queens at 40 cts. each; will be ready the first week in June.
S. H. RICKARD,
West Bridgewater, Beaver Co., Pa.

FOR SALE.—Mismated Italian queens for 50 cents each, or ten for $4.00. Twenty ready now.
J. N. COLWICK, Norse, Bosque Co., Texas.

FOR SALE.—2 or 3 hybrids at 25 and 50 cts. each, according to quality. With a pound of their bees, for $1 25 and $1.50.
C. WECKESSER, Marshallville, Ohio.

I have 5 mismated Italian queens that I will mail at 50 cents each, and guarantee safe arrival.
N. A. KNAPP, Rochester, Lorain Co., O.

Two black and three hybrid queens, at 20 and 25 cts. respectively, or the lot to one address for $1.00. Ready any time after the 1st of June.
LUTHER PURDY, Killbuck, Holmes Co., O.

200 Lbs. Box Honey Per Colony

GATHERED BY MOORE'S ITALIANS.

J. V. Caldwell, Cambridge, Ill., says: "As near as I can tell, the first season I had your queens they made me about 200 lbs. of box honey on an average."

G. L. Rinebold, Overton, Pa.: "They are very prolific; and, as honey-gatherers, they can not be excelled."

A. I. Root: "I can not remember of ever having a complaint of one of your queens."

FINE WARRANTED QUEENS A SPECIALTY.

Prices: Single queen, $1.00; per ½ dozen, $5.00. Safe arrival and perfect satisfaction always guaranteed. Send for new circular giving full particulars. 11d J. P. MOORE, MORGAN, PENDLETON CO., KY.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

PURE ✣ ITALIANS ✣ EXCLUSIVELY.

STOP, ✲ READ, ✲ AND ✲ ORDER.

Having determined to devote my time and attention exclusively to the production of pure Italian bees and queens, during the season of 1886, I offer, in order to reduce stock, **50 Choice Colonies of Pure Italians** in 10 Langstroth frames, guaranteed to contain at least 4 full frames of brood and 4 lbs. of bees in new chaff hive, at $10.00 each. I append my prices for the season.

My terms are cash with the order. First orders will be filled first. I will refund money at any time a customer may become dissatisfied with waiting.

My methods: One kind, and the best of that kind. Nothing except tested queens sold at any price. I will send one-year-old queens until stock is exhausted, and then this season's batch. I will commence to send, about May 1st.

1 tested queen	$1 00	1-frame nucleus, tested queen	$2 00
1 pound of bees	1 00	2 " " " "	3 00
1 frame of brood and bees	1 00	3 " " " "	4 00
		4 " " " "	5 00

In lots of 5, five per cent discount; in lots of 10, ten per cent discount. In lots of 10 or more nuclei or pounds of bees, I will pay express charges for the first 1000 miles. Now remember, I guarantee safe arrival and absolute satisfaction in all cases. Sample of live workers free by mail. Capacity, 25 queens per day after May 1st.

10tfdb **J. A. BATCHELDER, Keene, N. H.**

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or $2.00 per annum, when given once a month, or $4.00 per year if given in *every* issue.

$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or $2.00 per year.

Those whose names appear below agree to furnish Italian queens for $1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for $1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

HONEY COLUMN.

CITY MARKETS.

Cleveland.—*Honey.*—The market is very active on best white 1-lb. sections, which sell readily on arrival at 14 cts. Glassed 1-lb., and unglassed 2-lbs., slow at 12c. *Beeswax*, scarce at 25 to 28. Extracted, 7@8. A. C. Kendel,
May 20, 1886. 115 Ontario St., Cleveland, Ohio.

Chicago.—*Honey.*—The demand for honey is very light at present. Prices are easier; in fact, what little demand exists is confined to the best white comb in one-pound sections, at 15@16c. Extracted is held at unchanged figures. *Beeswax*, 25c for prime yellow. R. A. Burnett,
May 20, 1886. 161 S. Water St., Chicago, Ill.

Cincinnati.—*Honey.*—No change whatever in the honey or wax market since our last.
May 20, 1886. C. F. Muth & Son,
S. E. Cor. Freeman and Central Avenues,
Cincinnati, Ohio.

Kansas City.—*Honey.*—Honey of all kinds and grades is very dull indeed, and sales are slow. Prices are unchanged; 1-lb. sections, none in the market; would sell for 16 for choice white; dark, 12@14; 2-lb. sections, white, 11@13; dark, 9@10. Extracted, 3½@6. *Beeswax*, 23c.
May 22, 1886. Clemons, Cloon & Co.,
Cor. 4th & Walnut St's., Kansas City, Mo.

Detroit.—*Honey.*—There is no comb honey in Detroit to quote, and retail dealers are anxiously inquiring how soon they can get new. *Beeswax*, firm at 25 cts. M. H. Hunt,
May 21, 1886. Bell Branch, Mich.

St. Louis.—*Honey.*—Nothing new in our market on honey. *Wax* steady at 25c.
W. T. Anderson & Co.,
May 24, 1886. 104 N. 3d. St., St. Louis, Mo.

Boston.—*Honey.*—No change in price of honey. Sales very light. Blake & Ripley,
May 22, 1886. 57 Chatham St., Boston, Mass.

MR. JAMES HEDDON.

A SHORT BIOGRAPHY, FROM THE PEN OF PROF. COOK.

I AM very glad to accede to the request to give a brief account of the life and work of Mr. Heddon. True merit should always be rewarded; and as I am acquainted with no more able, thoughtful, studious, and hard-working bee-keeper in the United States than Mr. Heddon, it is with no little pleasure that I call attention to his life, his work, and to the valuable results of his careful experiments and thoughtful, studious labors in the apiary.

Mr. Heddon was the first specialist in bee-keeping in Michigan, and one of the first in the country, and thus his fertile, active mind has ever been directed toward the pocket-book side of bee-keeping; and so, as we should expect, all his work, experiments, and influence are right in the spirit of this intensely practical age. Best of all, from a long and intimate acquaintance with him I feel assured that all his labor, both of hand and mind, has ever been impelled by an honest purpose and sincere desire to advance the vocation of his choice.

It has often been remarked, that Michigan owes much of her reputation for push and enterprise to the fact that most of her inhabitants came from New England, many gaining wide experience from a short stay in New York. Mr. Heddon took advantage of one of these New-York sojourns, as he was born in the rich Genesee Valley of Western New York, Aug. 28, 1845. Thus he is now forty years of age. Like Patrick Henry he had no irresistible thirst for book-learning, much preferring his fish-hook, his gun, and a stroll in the fields and forest. Very likely this was owing largely to the faulty methods of the schools. Had the dull books of stupid text-book writers been replaced by the interesting things fresh from nature, how eagerly would this schoolboy have probed them to their very depths! No one can know Mr. Heddon without recognizing at once that he is a natural student. Given the right mental food, and how eagerly would he have swallowed, digested, and assimilated it!

In stature, Mr. Heddon is below the average, while his form is slight and wiry. He is extremely nervous, and his keen, intense expression, and spare, almost pinched features, would lead Mrs. Harrison to remark that he was fed on mince pie, ham, and sausage. But let me say that I have been there, and I know that excellent sense and the best taste and judgment rule in the Heddon kitchen. Mr. Heddon is gaunt and lean because he has a twenty-horse-power nervous organism in a ten-horse-power physique. His nervous tension and mental energy have always been vexed that their dwelling-house were not bigger and stronger, and are determined to destroy it; and it behooves our good friend to look sharply or they will succeed.

Mentally Mr. Heddon is exceptionally vigorous and gifted. The Rev. Mr. Gage once told me that he was especially interested in a certain young man in his village, who, with an opportunity, would certainly make a scientist. Years after, I became acquainted with this same promising young man in Mr. Heddon.

As a speaker, Mr. Heddon is unusually vigorous. His sentences are always to the point, and his figures and illustrations are often irresistible. I have known him at our State conventions to hold every person spellbound as he explained, often at great length, his experiments, views, and methods. The same spirited, forcible style characterizes his writings, as all who read the bee-journals know. His nervous energy, excessive love of fun, and desire for hard-earned victory, make him an eager controversialist. He fairly grows fat, mentally, in a good square honest intellectual wrestle. I have sometimes almost feared, I hope without reason, that his love of triumph made him to rejoice at the discomfiture of an opponent as much as in the victory of the right and true. I have also wondered if, as with most of us, prejudice might not at times warp his judgment respecting those who differed with him in view. His nervous temperament, and slight, overworked body, would make this possible. As he has sometimes written me in a complaining mood of some element in the bee-keeping world, I have thought of Christ's remark to Martha, "Thou art troubled about many things," and have wished we were all Marys who had "chosen the good part" that should not be taken away from us.

JAMES HEDDON, DOWAGIAC, MICHIGAN.

How many of us have found the door to a delightful life, in the most beautiful and charming girl of the world! This was doubly true of Mr. Heddon. The "sweetest girl in the town" not only provided Mr. H. with one of the happiest homes in the State, but led him into apiculture. Miss Hastings' father was a bee-keeper, and with him Mr. Heddon worked one year. No wonder he advises all to take a year with an experienced bee-keeper. If he will furnish conditions like those of his own apprenticeship, I think few young men will hesitate. As little wonder that he looks so fondly on the "gude wife" when she took him from the dull routine, machine-like life of the clerk, into the active, pleasant, intellectual life of the apiary. This loving wife has been Mr. Heddon's only partner for the seventeen years of his bee-keeping experience.

Mr. Heddon has told me that he commenced bee-keeping with nothing except a stout heart, and he had given this away to that "sweetest girl." He has been a specialist all that time, except for a brief period of late, when he has sold supplies. This diversion he has told me was a loss to him. Now he is worth thousands of dollars. He went into the supply business in 1879, in hopes that, by a circular, he could answer many of the questions that now came to him in letters, and save time to his business. His present capital he credits almost exclusively to honey production. He has had as many as 550 colonies of bees at one time, which were kept in three separate apiaries. He now has 450 in two apiaries. In 1877 his Glenwood apiary, worth $1500, and numbering 99 colonies, gave him a cash income of $1070, and increased to 207 colonies, all but two of which came through the following winter in good condition. The expense in caring for this apiary that year was $200. One year, with 16 colonies he increased to 33, and sold $800 worth of honey. All of the 33 colonies wintered the succeeding winter. At that time honey sold for a very high price. His largest yield for one season, of a single colony, was 410 lbs., all but 48 of which was extracted. He once secured 29 lbs. 13 oz. of unripe extracted honey as the result of a single day's gathering of a single colony.

Of course, all has not been smooth sailing, as he has as large stories to tell of winter losses. He thinks the winter of 1884-'5 snatched $1800 from his pocket-book; yet he murmurs not, as he thinks that winter solved the difficulty, and he will lose no more. We all hope he is correct.

Mr. Heddon is very neat and methodical. It is a very great pleasure to visit his place. I think I never visited an apiary where more taste and good judgment were displayed in all the arrangements of the bee-yard.

The valuable improvements which Mr. Heddon has given to our industry are many, and will most interest the readers of this sketch. All that I shall name, I feel certain are original, and nearly all I know to be excellent, from actual experience.

I have found the slatted honey-board a very valuable adjunct to the Langstroth hive. This, when made just right, keeps the sections perfectly neat. The spaces must be just over the center of the top-bars of the frames in the brood-chamber, and the spaces between top-bar and slats no more nor less than a bee-space. This prevents the brace-combs, and such a honey-board needs only to be tested to be retained in every apiary. His modification of the Langstroth hive, omitting the portico, the telescopic upper story and cover, and the bevel of the Simplicity, have so pleased me, after a two-years' trial, that I would never think to return to the old styles. Those who condemn, surely have never tried it. The shade board is also much superior to tree, evergreen, or grapevine.

Like myself, Mr. Heddon used sections before he ever saw them elsewhere. Though original with us, their use in our apiaries may not have priority.

Mr. Heddon's shipping-crate, as I state in my book, is neat and cheap, and was the first substantial improvement in that article.

The section-crate, with bee-space above and below, will probably never be excelled in securing comb honey without separators. After two years' use I pronounce it simply perfection. I was almost disappointed in not seeing it in the new hive.

I have already reviewed the new book, and there spoke of the new hive and system. There can be no question of the originality of these, and hardly less that they are a marked improvement and will soon come into general use. I have never tried these, but the experienced bee-keeper does not need to try every invention to be assured of its excellence.

Mr. Heddon has also practiced the principles of breeding, as followed by our successful breeders of other domestic animals; that is, he has crossed two valuable breeds, and by selection has secured a strain, with the excellences of both the original races, and without their undesirable qualities. He claims this; and while I have not tested his improved strain, I am certain that the above is the method which must be employed to secure the best bee.

Lastly, Mr. Heddon suggested the "Bee-keepers' Union," which may and will be of great service to our industry. Each of us is liable to prosecution by those ignorant and prejudiced, and we need just such an organization to aid us in protecting our rights, and in maintaining the high position which our industry deservedly holds among the pursuits of the world.

Mr. Heddon has been President of the Michigan Association, and a very poor one he made. A president must be staid and serene, and without nerves, which does not describe our Dowagiac friend.

I wish I could say just how many children our friend has. This I know: That when at his house, some years since, among the many attractions I saw were some very beautiful children, those best ornaments in every home. A. J. COOK.

Agricultural College, Mich., May, 1886.

RAISING PLANTS FOR HONEY ALONE.

FIGWORT.

IN the spring of 1883 I planted an acre of figwort roots on rich, low ground. The ground was well prepared, marked both ways as for corn, and the plants came up finely, scarcely one missing, although a good share of them were shipped from Medina, Ohio. Part of them I found growing near home, and these were transplanted, with no chance for drying the roots. I don't know that I could see any difference in the growth of these latter and the ones that were shipped. They were carefully tended, the same as corn, with cultivator and hoe, grew finely, and, a little before white-clover bloom was over, came in bloom nicely. When in full bloom it was a fine sight to see how thick the bees were upon them. I can not say how much honey the acre yielded, nor what was the quality. I have often wondered how it could be determined so accurately what quantity of honey could be obtained from a given amount of pasturage; and the quality, where the resource is limited. I am of the impression, that, to be profitable, a honey-plant that yields no other crop must be able to hold the ground after the first year, without any cultivation, so the second year my field of figwort was left untouched. It grew finely, and blossomed as profusely, if not more so, than the first year. Some weeds grew up among it, but not a great many, as it had been kept as clean as a garden the preceding year. The weeds seemed to do little or no harm. Thousands of young plants came up this second year, from seeds dropped the first summer. I let them all grow, holding rigidly to the plan of leaving the ground to take care of itself. I looked with some interest to see whether the next, or third year (1885), the young or old plants would do the better. But I looked in vain. Neither young nor old showed a leaf. They were dead, root and branch. Would they have lived better on different ground? Sweet clover lived through, side by side, on the same ground. Would they have lived through if the winter had been milder? It was, perhaps, the severest winter ever known here. Would it have done better if the ground had been partly occupied by grass? Where I have seen it growing wild, it has been in thick grass (although I have seen very little thus growing), or on ground more or less shaded. Would it take care of itself in a basswood grove?

MELILOT, OR SWEET CLOVER.

This is imported under the name of Bokhara, although some think there is a little difference. Perhaps the principal difference is, that the imported seed is cleaned of the hull; the domestic, not. For years I have known little patches of melilot on the roadside, or elsewhere, that seemed to take care of themselves from year to year. Moreover, from all I have read about it I thought I had a right to infer that it would grow and prosper anywhere, simply by scattering seed there. Now, however sure it may be to grow under the most adverse circumstances, and prosper with the most provoking persistence where it is not wanted, there is possibly such a depth of ignorance and bad management as to wither even the ambition of sweet clover. I have spent perhaps $40.00 in trying to get a fine stand of it, and am compelled to say it has been mostly a failure. Before I forget it, I want to say that, so far as I have observed, the quality of soil seems to have little to do with the success of this plant. Perhaps the rankest growth has been on yellow clay, or subsoil thrown up, where nothing else cared to grow; but possibly the very fact that no other vegetation grew there gave the melilot a better chance. I have, however, seen nearly as good growth on bottom land, with rich soil. I reasoned that, as the volunteer patches had no care from year to year, simply the seed dropping on the ground through the fall and winter, if I imitated this, success was certain. So, when a light snow was on the ground I sowed some 20 acres, including ground in almost every condition. Some of it was pasture, some sod which was not pastured; some, ground which had been in other crops, some very rich, some so poor that it was as bare of vegetation as the middle of the road. In this poor, bare ground, occasionally a seed grew, perhaps a rod apart; but what did grow was strong and vigorous. On a bank of yellow clay, thrown out in digging a cellar, was a pretty good catch, and some seed came on ground which had been cultivated, especially on the low ground, adjoining the figwort. I do not know that a single seed grew among the grass, either pastured or not. This seems strange to me, for I have seen it growing well in grass where self-sown, and I can not see why, in all these acres, none came. I have done nothing since with any that did come, and it has held its own, and in some places has increased to five patches, perhaps, in all, covering an acre or more. Some that was covered lightly with a hoe in the fall did pretty well. Mr. Root, I think, recommended sowing with a drill. I believe it would be an improvement. Where it is self-sown, only a few out of thousands of seeds grow; and if covered, more might grow. I had better success sowing on the roadside. Of course, it could not grow in the middle of the road, but on the edge, just at the line of demarcation between the road and the grass, it did well. In general, what fell among the grass never came; but there was one place where it grew well for a long distance right in thick grass. The only way I can account for its growing just at the edge of the road is, that at that point the wheels in a muddy time would imbed the seed in the ground, but not run over it enough afterward to prevent its growing. The place where it grew in the grass was one where wagons were sometimes driven, especially in a muddy time, but never traveled enough to kill the grass.

One spring I had a piece of ground nicely prepared, and sown with oats. After the oats were dragged in, melilot was sown, and I can not tell now whether it was brushed in or not. It came up well, making a very nice, even stand, but pretty thick on the ground, if it should stool out any. The next spring I looked with eager interest, almost before it was time for it to start, but could find very few stalks starting. Later I could find but few, and their roots seemed coming out of the ground. By the time it should have shown big stalks, not a sign of one was to be seen on the ground; and although the ground has since been untouched, not one plant has appeared, the ground being well covered with clover and grass, which came up of itself. Was it because the ground was so nice and mellow, that the frost heaved out all the melilot? If we had a drill that would plant in hard ground or sod, would it be a success? C. C. Miller, 340—226.

Marengo, Ill., May 20, 1886.

Friend Miller, we are very much indebted to you for the facts you have given. I did not know before that anybody had ever started out on so extensive a scale as 20 acres of any one single plant, for honey alone. Your experience in figwort is about like my own, only mine didn't all die the third year. The plants got rusty and sickly, and sort o' dwindled away. A new plantation, now in its second year, is looking beautifully. I agree with you, that it is very difficult indeed to tell how much honey we get from a certain plant. I have sometimes thought I should like to find a locality where there was absolutely no yield of honey at all; then I would have an acre of figwort for, say, four or five colonies of bees. If these bees gathered honey, and filled sections while the figwort was in bloom, and gave nothing as soon as it was out of bloom, we could tell something about it. Our efforts to cultivate sweet clover were also a good deal like yours, although one patch on poor ground showed, the second year, during the months of May and June, such a beautiful stand that farmers came to see it for some distance around, and it was a good deal talked of as a forage plant.

There is something funny about this whole matter of nature and art. Plants that have been cultivated for years, like wheat, oats, corn, etc., behave correctly, and almost invariably thrive under artificial treatment; but plants that have always been wild, some way don't seem to take kindly to artificial methods; in fact, they die under the best of care; while if let alone they thrive wonderfully. If we closely look into the matter, we may, perhaps, find some little trifling thing that upsets the whole experiment. Just now I am a good deal puzzled about my poultry. A hen that has the range of our whole 18 acres made a nest on the ground, under a lumber-pile, and she hatched every egg but one; and more than that, she went off with her eight chickens, without a bit of care from anybody. When they were four or five days old she was discovered off by herself, with every chick as bright and brisk as a cricket. They didn't have any corn meal nor cracked wheat, nor bread and milk, and yet they seemed to be good for a half-mile tramp, chasing their mother. Well, in my nice poultry-yard with all its modern appliances, I get only two or three chickens from a setting—sometimes not a chick. Last season I feared my Brahma rooster was bad, and so I bought a higher-priced one; but it does not make any difference. Old Dame Nature beats me all to pieces. The fowls that have the run of our whole 18 acres board themselves, lay eggs, and raise chickens; expense, 0; income, a good lot of eggs every day. Your expression, "depth of ignorance and bad management," some way seems to fit me tiptop. Well, I think I know where the truth is. If we try hard enough we can assist nature; but if we don't look out, we shall be only stumbling-blocks. May God give us wisdom in our work with honey-bees, honey-plants, poultry, stock, and all these other wonderful and necessary gifts to his children!

THE FIRM OF JANE MEEK & BROTHER.

A Serial Story in Ten Chapters.

BY REV. W. D. RALSTON.

CHAPTER VI.

A TALK ON SWARMING.

AS the Meek family gathered around the dinner-table that day it would have been difficult to introduce a conversation on any subject but bees, all were so excited by what had occurred. The reader might be interested in some things there said.

Jane remarked, "It was too funny to see the bees pouring out of the old nail-keg, as they seemed so very anxious to get out; they seemed as if anxious to leave the old hive. It seems strange to me that they should want to leave the old hive, which has plenty of honey, and go out into the world without knowing whether or not they could find a hive or hollow tree in which to live."

Her father replied, "In like manner I have often wondered that a young lady will leave her father's house, nicely furnished, where she can have all her heart could wish, and go away, often to a distant State, with a young man who is not able to afford her even a comfortable house."

Jane said, "I will never do such a thing. I will always stay with you and mamma, and my dear brother Tommy."

Said her father, "You no doubt feel so now; but I think when you are a woman you will change your mind. At least, I could hardly expect that you would do differently from what your mother did; and I know she left a nice comfortable home, the society of parents, brothers, and sisters, and came away here with me, a poor minister, who had no home of my own to offer her."

Jane replied, very innocently, "But then, it was to live with *you*, papa; I would go anywhere to live with you; but I will never leave you and ma, and go anywhere to live with a strange man or boy."

Mr. Meek looked over at his wife. There was a smile on the faces of both. He then said, "I think it is this way about the swarming. God has planted in the heart of all living things a desire to multiply their kind. Bees multiply by swarming. When they become numerous in the hive, and begin to be crowded for room, they swarm, and thus form a new colony."

"I wish, papa," said Jane, "you would tell us all about bees swarming, for to me it is a very strange and curious thing."

He accordingly began. "I have told you that the queen is not the ruler of the hive. If there are rulers in it, I think they are the busy little workers. I imagine some pleasant day, when honey is coming in nicely, and the hive is rapidly increasing in population, a number of these busy fellows put their heads together and ask each other, 'Don't you think we had better have a swarm?' All present being of that mind, they then pass through the hive, saying, in bee-language, to every one they meet, 'We must prepare for swarming.' Well, the first preparation they make is to begin raising drones. The queen lays two kinds of eggs, called drone and worker eggs. Bees also build two kinds of comb, called drone and worker comb. The drone-comb has larger cells than the worker, and in it drone-eggs are laid, and in it drones are hatched. Both kinds of comb are also used for storing honey and pollen. If the bees have no thoughts of swarming, the queen either does not lay in drone-cells, or, if she does, the bees destroy the eggs. But when once they get what is termed the swarming fever they are as careful of the drone as of the worker brood. The next step is to construct queen-cells. These cells are very different from the other two kinds. They are placed in an opposite direction on the combs, the open end being downward, and they are never used as store-cells. The queen either lays worker-eggs in these cells, or the workers remove eggs into them. Queens can not be hatched from drone-eggs. It is believed that it is the kind of cells in which queens are hatched, with the kind of food given them by the workers, that makes them queens. When bees want to raise a queen they are not satisfied with one merely, but build a number of cells, and raise a number of queens. For a time after the queen-cells are formed, the queen does not seem to pay any attention to them. Eight days after the eggs are laid, the young queens are large enough to be sealed over. It is then that the first swarm comes off. The old queen, impelled by some motive, leaves the hive, accompanied by a great number of bees, and form what we call a swarm. Remember, the old queen always goes with the first swarm."

Tommy here inquired if the queen Mr. Brown gave them in the nail-keg was now in the new hive.

His father said she certainly was, unless she had died, and the bees had raised another to take her place.

"There is no queen in the nail keg now, but there are little baby queens in their royal cells, or cradles. In eight days these cells will hatch, and then probably a second swarm will come from the old hive."

"Oh! I remember," said Jane. "The book tells us that, if we put our ear to the old hive, just before the second swarm comes off, we can hear the queens saying peep, peep; just like little chicks when they chip their shells, and I will hear them if I can."

Her father continued. "The first queen that hatches out wants to tear up the other cells and kill the young queens in them. She may then depart with the second swarm, which is always a smaller swarm than the first; and, if the weather is favorable, it may be expected on the eighth or ninth day after the first. If there is a third swarm it will probably be the same day or the second or the day following. It will be still smaller than the second. There ought to be no third swarm, and it would be better if there were no second; but the bees in a hive seem at times to be seized with this swarming-fever so badly that they will swarm until the old colony is almost broken up."

"I should like to ask you, papa," said Jane, "if bees hunt up a future home for themselves before they come off as a swarm."

"That is a thing not positively known," said her father; "but the general belief is, that bees swarm, and settle as ours did to-day, and then a company start out as scouts to look up a new home. If the swarm is hived before long, and the hive then removed to its stand before these scouts return, all is well; but if not, and the scouts find a tree, and then return to the colony, they may induce it to leave the hive and go to the woods, even after it has been hived. It is certain that some colonies go to the woods without having selected a tree, and there cluster upon some branch until a tree is found. There are also other instances that seem to indicate that the bees had their future home selected before they swarmed. Hence I say your question is one I can not answer. I think if an apiary is properly watched during swarming time, the swarms hived in nice cool hives, and then shaded from the sun, not very many colonies will leave for the woods. Still, there will be one now and then, notwithstanding the greatest care. Usually those losing many colonies are careless persons. Their bees swarm unnoticed, hang until tired out, and then leave for the woods. Or they are hived, and then placed in the sun without a particle of shade, their new combs melt down, and they leave for the woods."

The next day at dinner Mr. Meek said to the children, "That was a large swarm, and it ought to make us some surplus honey. I want you to make ready a case of sections, and place it on their hive."

The children were eager to do this; but of course their father had to show them how to do it. They first brought a rack, and enough sections to fill it. Each rack held eighteen. They then selected eighteen pieces of thin foundation, and dipping the end of each piece into a melted mixture of beeswax and rosin, which their father had prepared, they quickly placed that end in the center of the top piece of a section, and held it there for a few seconds until the melted wax cooled, and securely fastened it. Thus they prepared the entire eighteen. They next arranged them in the rack, with boards on each side, and separators between each row of sections. The three rows had the appearance of three ordinary-sized honey-boxes, only differing in the manner in which they could be taken apart. Mr. Meek had directed this work, and now with a wedge-shaped strip he pressed them firmly together, and they were held so.

The smoker was then lighted, and a little smoke blown into the entrance of the hive. After waiting a few minutes he took away the cap, while Tommy, with a screw-driver, loosened the boards over the frames, and removed them. While he was doing this Jane used the smoker, blowing a little on the bees whenever they showed any signs of becoming excited. Mr. Meek looked at the combs which had been already started, and said they were being built straight. Tommy then placed the case of sections on the hive; and when all was nicely arranged Mr. Meek replaced the cap.

To be continued July 1.

SOMETHING ABOUT HONEY FROM THE SPANISH NEEDLE.

ALSO SOME HINTS IN REGARD TO GETTING RID OF SMALL ANTS.

FRIEND ROOT:—Like a general in the army, you seem to be "headquarters" in apiculture, and are continually receiving reports from all along the line; but, *un*like the general, you send those reports right back so that all may know what is being done.

I live near the middle of a prairie—being about two miles from timber on two sides, the other two sides being treeless except orchards, which are quite numerous. I have but a few colonies of bees; and when the bees have to go to the timber for pasture I find those near the timber are more prosperous than mine; but during the smartweed and Spanish-needle bloom, which are our principal honey-plants here, my bees excel others' in producing honey. The condition they are in at the beginning of the honey-flow may have something to do with it, as I endeavor to have strong colonies at that time. The Spanish needle of which I speak is different from the Spanish needle in States further east. It has a yellow flower, and the seed is broad and flat, with a needle-like projection from each corner at the outer end. The length is about the same as those of the other variety of Spanish needle. The honey has a yellowish tint, and is of a nice rich flavor. I do not find this plant mentioned in the dictionary, and it may have some other name; but I know of no other, and I mention it particularly because of its abundant yield of honey. We have some white clover, but not enough to get surplus honey from. Some of our bee-men are having alsike clover seed sown by way of experiment, to see whether it will be profitable.

In this section, as far as I know, wintering is generally done on summer stands, with little or no protection, except a fence or orchard for a windbreak. I know of one man who set posts along the west side, to the tops of which he nailed a board, and against which he stacked corn-fodder. His buildings served as protection on the north. I might add, chaff cushions are used by all practical beekeepers within my knowledge.

Last season was not a good one for honey—about one-third of a crop, or 40 lbs. per colony, being a fair average. The increase was not enough to make up the mortality of the previous winter.

I notice in the reports that some are troubled with little red ants in bee-hives, eating queen-cells, etc. No person who has not had experience knows, or can form any idea, what a trouble and pest these little ants can be. They will get in the cupboard, and are especially fond of light bread, pies, cookies, etc. The good housewife may set the legs of her safe in water; but if one of the cups becomes dry, or she leaves the broom leaning against it, or it touches the wall in any place, she is horrified to find the little red creatures have invaded her pantry. If there is any thing in the world that will make a woman scold, it is red ants. She may brush and rub and scrape and scrub, only to have a new army as soon as the shelves are dry. Some one said in GLEANINGS, "Treat the nests with hot water." But whoever saw a red-ants' nest? They must have had a microscope. Why, I should think half a dozen full-grown red ants could get on the head of a common brass pin, and not be crowded either. I judge they can smell, but they must have a small nostril. I don't know how they can find sweets so readily unless they can smell. Last summer they got in my honey-house, in my honey, and among my bees. The first thing I did was to clean out my house—emptied it of every thing, and gave it a thorough cleansing with soap and water. When it dried (as it soon did) I saturated the floor with kerosene, and was afterward careful not to let honey-cans touch the side of the building. I was not bothered with a red ant there afterward. I then saturated the bottom-board and lower edge of a hive, and was troubled no more in that hive. We took covers of glass cans and set under safe-legs, and filled the cups with the same liquid. It is soon absorbed; but about two applications are sufficient

to keep these pests away for a season. The scent of the oil seems to be obnoxious to them, and they will not cross where the oil has been applied. Let those troubled with red ants try coal oil, and report success.
GEO. WISEHEART.

Iola, Clay Co., Ills., Feb. 22, 1886.

MOVING BEES IN THE DEAD OF WINTER.

NOT ALWAYS FATAL, AND SOME OTHER FACTS IN REGARD TO THE MATTER.

IT struck me that a report in regard to my success in moving bees during the past and previous winters might not be out of place, as there seems to be a great aversion to moving an apiary during the cold season. I commenced bee-keeping with one swarm in the summer of 1881. This was moved about Christmas, by sleigh, a distance of about 12 miles. It was in a hive holding a frame about the size of the American.

The summer of 1882 found me with 4 swarms, the first having swarmed three times. These I fed about 40 lbs. of granulated sugar, having previously taken about 12 lbs. of honey. I packed them in boxes, leaving about 6 inches on all sides, filled with cut straw. I again moved, about New Year's, 12 miles, and again in April, 1883, 3 miles, in each case by sleigh. The four colonies wintered well; and during that year I transferred to Simplicity hives and increased to 14, with 303 lbs. of surplus honey. I fed 73 lbs. of granulated sugar, and moved all colonies in October, 1883, 5 miles, to the railroad station, and thence per car 30 miles.

After moving I transferred all to chaff hives (Root's). I found a great many bees had died in transit; having left the quilts on, the bees had forced their way above, and had either died of starvation or suffocation. The day of moving was very warm. Three of these succumbed during the winter of 1883, leaving 11, spring count. During the summer of 1884 I increased to 22, taking 475 lbs. of surplus honey. I fed 142 lbs. of granulated sugar. These were moved again in October, by wagon and car, a distance of 80 miles; 14 were in Root's chaff hives, and 8 in Simplicity. The Simplicity I packed in straw clamp.

A large quantity of very dark honey was gathered during the fall, which I took to be goldenrod, as the blossom of that plant was particularly profuse that season. Soon after Christmas the bees began to show signs of uneasiness; many were evidently affected with dysentery, and on the slightest moderation of the extreme cold they came out and dropped from the alighting-board on the snow. During the mild spell at the end of February, I found that 16 were dead; the remaining 6 were all either very weak, badly affected with dysentery, or both. I fed the survivors candy. When I again examined I found that all were gone. My consolation was, that I was not alone, and that bee-keepers near by, with five times my length of experience, had suffered a similar loss. I took heart of grace, and in the spring of 1885 I sent for 4 four-frame nuclei from Viallon, and some queens from Root. The first nucleus proved a complete failure, through a young queen being hatched out, and the old one being destroyed. From the other three were built up 11 good colonies. I took 360 lbs. of honey, extracting all after the flow had ceased, and then fed 287 lbs. of granulated sugar made into syrup.

In view of the fact that I intended to move the bees again during the coming winter, and the loss of the previous winter, I took particular care in fixing up. Having raised the frames about 1½ inches higher than their summer position by placing blocks under the shoulders of frames, I contracted the brood-chamber to about two-thirds of its usual size, leaving half the number of frames properly spaced. I then packed chaff behind the division-board, pinned the frames to the blocks with large tacks, arranged a space above the frames, covered with cloth, then packed loose chaff to fill the upper story of the chaff hive. On the first of February this year, the hives were removed one mile and a half to the car, remained 2 nights and nearly 2 days on board, during the coldest snap we had last winter. They were then removed from the railroad station, stored in a room for two days and nights, then moved to the open air, the snow piled up on the north-east and west sides, with a slight covering over the entrance on the south. They were then moved again April 5. On examining them I found all in excellent condition, queens all present, raising brood, and very few dead bees; in some hives there were none at all.

I hope not to have any more experience in moving bees in winter. I thought this report might be of some benefit to any who may find it necessary to do so. I was much inclined to sell rather than move, but selling would have been the more expensive way out of the difficulty.

T. CHAPMAN GRAHAM.

Wingham, Ont., Canada, May 3, 1885.

Friend G., I should think you had had experience enough in moving bees in the winter time. If I were you I think I would stop moving bees or else stop keeping them. We value the facts you furnish, however.

THE LOCATION OF AN APIARY.

THE IMPORTANT BEARING IT HAS UPON SUCCESSFUL WINTERING.

MY experience corroborates the words of Mr. France, on page 352 of the current volume of GLEANINGS, where he says: "In the location of an apiary I am satisfied that a great deal of our success or ill success comes." My home apiary is located on the south side of our barns, and near enough them to be protected from the north wind. The other sides are partially protected by an orchard. Here I have wintered, on an average, 78 colonies during the past six years; and, with the exception of winter before last, when 12 out of 117 starved to death, I have never lost a colony. Last fall I packed 155 colonies in this yard, and I have 152 at present, one having been stolen during the winter, and the other two being queenless.

My hives are in rows running east and west, and quite close together; and it is a noticeable fact that the outside row on the south contains nearly all my poorest colonies. It seems almost incredible that one row of hives should furnish appreciable protection to an adjoining row, yet I am unable otherwise to account for the great difference between this outside row and the rest of my colonies.

Two years ago I started an out-apiary. Not appreciating then, as I do now, the importance of a good windbreak to an apiary, we selected ground which slopes to the east and north-east; and where both the north and south winds have an unimpeded sweep. Winter before last we lost one quarter of our bees in this apiary, while most of the others came through mere wrecks. The past winter, one-sixth were lost, while many of the rest are in poor condition. Furthermore, the upper row of hives in this apiary is placed along a brush-grown fence which affords it very material shelter from the north-west wind. And it is a fact that this row of hives came through both winters in much better condition than any other.

Now, if it is true, as I believe it is, that successful wintering is dependent very largely on the protection which the location affords, we have one explanation of the diverse results which often come from otherwise similar methods. So long as my experience was confined to my home apiary I did not realize how much my successful wintering was dependent on my sheltered location; and had I written an article on the wintering problem I would have dwelt almost entirely upon my method of feeding, preparing, and packing my bees for their winter repose, while the chief element, as I now believe, in my success—the mere accident of a sheltered location—would probably not have been mentioned.

This has been the best spring for giving the bees an early boom that we have had since I have kept bees. For ten days in April we had summer weather which forced fruit-bloom along at least two weeks ahead of its usual time. It is already on the wane, while in other years it has usually been only fairly begun at this date. Last year, hard maples were fairly opened for honey-gathering on the 9th of May; this year, the bees were roaring among them on the 22d of April. JAS. MCNEILL.

Hudson, N. Y., May 10, 1886.

BEE-STINGS FOR RHEUMATISM.

AN EXPEDITIOUS WAY OF APPLYING THE MEDICINE.

THE following article was written by my friend Wm. Vennamore, for the Maxwell *Tribune*. I had advised him to use the bee-sting cure for his rheumatism; but I didn't suppose he would put a "small paper sack well filled" up his pants leg. It has caused ever so much laughter and merriment here among the neighbors; but his rheumatism has disappeared.

D. E. BRUBAKER.

Maxwell, Storey Co., Ia., May 15, 1886.

Mr. Editor:—I have been afflicted with rheumatism for some time, and have tried most of the remedies said to be good for such disease, but received little benefit. One day last week I thought the good Samaritan had come, in the person of Mr. D. E. Brubaker: perhaps you are acquainted with him; he has a bee-ranch south of town; a clever fellow, too, he is. He told me bee stings were the best thing in the world for rheumatism, and if he should ever have it he would try the bee remedy sure. Thinks I, we've got the medicine right here at home, and it won't cost any thing, and I will just try a few: I think people as a rule take too much medicine any way; better try more home remedies. So, provided with a small paper sack and some courage (for I must confess I was always a little careful not to disturb bees, for it hinders them from gathering honey, you know), I held the open sack at their entrance and soon had it well filled with the buzzing creatures. I then made straight for the house and gave sack and bees to wife and held open my pants leg and said, "Now start 'em up." She pushed sack and all up arm's length, and laughed a little, and asked, "Are they going?" Says I, "You bet!" Just then one administered, and I grabbed for him (as is natural on such occasions), and from that every last one laid to, and four doctors with eight resurrecters couldn't do business so lively as those bees did. I, in a rather commanding manner and tone, screamed for wife to take 'em out, but she seemed to be slow about it, so I got out, and left breeches and bees in the same room, and I went to bed in untold misery, and two times as mad to think I would try everybody's remedies. After this, others can try bee-cures and bee-*men's* remedies, and I will try Hostetter's or McLlain's remedies. HAY SEED B.

Friend B., the principal point to me in the above little sketch is, that the rheumatism has disappeared. I am inclined to think, however, a smaller dose would have answered every purpose. Many of our readers will remember the facts that have been brought forward in our back volumes. I think that it is pretty well settled that poison from bee-stings is many times a cure for rheumatism.

SMALL COLONIES, AND MOTH WORMS.

THE REASON WHY A SMALL COLONY CAN NOT STORE AS MUCH HONEY PRO RATA AS A LARGE ONE.

IT is said by some, that a weak or small colony will store as much honey, pro rata to the number of bees, as will a large one; but I think this has not been clearly proven. To substantiate the theory, it is argued that a colony having two combs of brood, and bees enough to cover them, being placed in a full hive of combs, will store as much extracted honey in proportion to their numbers as will a full colony having eight frames of brood in the lower story, the same being tiered three or four stories high. The argument holds good in all except one particular, and in this it is very deficient. Let us look into their workings a little. The full hive has brood to the capacity of the queen, so that the tiering-up of the other stories on top does not increase the amount of brood any, especially when a honey-board is used so as to prevent the queen going "up stairs." Thus the bees have only so much brood to feed as the storing advances, and the colony has a large force of bees in excess of their brood.

Well, how about the small colony? The queen has brood to only about one-fourth of her capacity, while the brood is in excess of the bees — so much so that I have often seen 500 bees keeping from 3000 to 5000 of brood; and as in the small colony the queen is not restricted as to egg-laying only by the number of bees, her brood advances in excess of the mature bees all the while until the limit of the hive or her capacity is reached. Then we find these few bees struggling hard to supply the wants of the brood all through the honey-harvest, so that, when said harvest is as short as it is here, the result proves to be, at the end, little or no honey, with a host of useless consumers raised from this brood to eat the little honey the small colony have succeeded in laying up. I think I have made the matter so plain without further enlargement, that all will see the force of the argument, and have all strong colonies by uniting the weak ones, or otherwise building them up early. If the queen could be restricted to only the two combs, then the pro-rata yield might hold good; but where would the bees come from for wintering? Strong colonies at the time of the honey-flow is about the only thing that can give the apiarist any assurance of success. Because the Syrian race of bees will not build up with me before the honey-harvest, and commence to breed rapidly as soon as it does come, so that they work on the same plan as does a small colony, is the reason for my discarding them. That the Italians will give more bees at just the right time, and less at all other times than any other variety, is the reason for my preference for them.

MOTH-WORMS.

Lately I have been reading that moths "will never breed in combs that contain no bee-bread," the idea being advanced that, if no pollen is contained in our section honey, we need have no fear of the larva of the wax-moth injuring the nice cappings of the combs. I wish that such were the case, for then no one need fear the moth in section honey, as those containing pollen could be left with the bees to care for till late in the season, or treated with burning sulphur. Quinby says, page 144 of his "Mysteries of Bee-Keeping," "Worms work only on the surface, eating nothing but the sealing of the cells;" again, "*Wax, not honey, is their food,*" and tells us all about how we must destroy these worms, unless we would have the nice cappings of our cells destroyed. From former years' experience I know that boxes of surplus honey have had all the sealing to the cells eaten off by the moth-larvæ, when not a cell containing pollen was to be found, while a friend had nearly one-half of his surplus honey ruined for market in 1874 by not knowing that he must look after the worms. I have seen moth-larvæ thriving both between sheets of fdn. and cakes of wax; and I know that this pollen theory regarding the wax-moth is not—but, hold on! At Detroit, at the National Convention, this same theory was advanced in a discussion of this question, to which I listened very attentively. One brother stated that he had found worms living in a box of wax, when the strongest advocate of the pollen matter told us that there was no wax on the market, or to be found, which did not contain pollen. So it would seem that there is no use for me to say any thing regarding what I am certain of, for there is pollen everywhere, so it matters not whether side-storing or top storing is adopted, as there is pollen enough in the wax of our comb to breed moths. I wish to say, however, that, as a rule, I get more cells of pollen in the boxes at the top of the hive than I do in those at the sides, and in neither place do I get pollen enough to be seen or tested in more than one section out of 300. One thing I am glad to say, which is, that we have little trouble in this locality now with moth-worm to what we did ten or fifteen years ago; and had Quinby lived to write his book at this time, instead of 1865, that chapter concerning the case of box-honey, to keep it from the moths, would probably never have been written. Still, it is always well to keep a good lookout for this pest, and I give this warning in time, so none need be "caught napping." G. M. DOOLITTLE.

Borodino, N. Y., May, 1886.

Friend D., if I have ever taken the position that a nucleus would store as much honey as a full colony, I think I must have been off from the track. Circumstances, however, might have something to do with it. If a nucleus were made of frames of brood taken from a full colony, there might be a period when the bees from this brood would be of just such an age that they would gather honey equal to a full colony, in proportion to their numbers. At such a time, when a young queen commences to lay, before they have larvæ to nurse, I do not know but that they might, for a few days, gather more honey than a full colony. I have often noticed weak colonies, however, that became weak from spring dwindling (when there were not bees enough to properly care for the brood) that would gather hardly enough stores to keep them from starving, when full colonies were working heavily in boxes. I remember one spring when the bees were so cross, just before the fruit-bloom, we could hardly open a hive, or do any thing with them. Well, fruit-bloom, came out and every thing was lovely —bees were gentle, and easy to handle. But one day I came suddenly upon a colony that was so ugly it seemed to me they could not have had notice of the abundant yield of honey evident in every other hive; and, come to get the combs out, sure enough there were so few bees that could be spared to go into the fields they had hardly a drop of new honey, and were as cross as if none had come at all.

In regard to moth-worms and pollen, I feel quite well satisfied that moth-worms are a good deal worse in combs containing some pollen, although I presume likely they often work to some extent in combs where little or no pollen is visible. I have never seen moth-worms on combs of newly made foundation; but one of our customers reports finding moth-worms among sheets of foundation laid away in a box. In this latter case it is evident they were feeding on beeswax; for if any pollen should stay in the wax through the operation of melting and dipping, it must certainly be in extremely minute quantities.

SUB-EARTH VENTILATION.

SOME FACTS IN THE MATTER BY ONE WHO HAS PRETTY THOROUGHLY GONE OVER THE GROUND.

FRIEND ROOT:—I see that you and a number of your correspondents are considerably exercised over the subject of sub-earth ventilation. Mr. C. C. Miller has an inquiring and suggesting article in April GLEANINGS, pages 258–'9, in which he is investigating the matter by experiment. This ground was all explored years ago by Prof. John Wilkinson, whose place of residence, some six or seven years ago was in Brooklyn, N. Y. Prof. Wilkinson is a civil engineer, and he patented a process of warming buildings by a system of sub-earth ventilation. He applied his system to dairy-rooms, stables, and barns, and proposed introducing it into dwellings. In fitting up a dairy cellar, to get the most perfect results the walls were insulated by studding inside, and lining with building-paper, thus creating a dead-air space between the paper and walls. The depth of the ventilating-pipe varied from 5 to 12 feet. In New York, and latitudes further north, 5 feet was deep enough for summer ventilation for a dairy-room. In the latitude of Topeka, Kansas, where the hot south winds blow almost constantly through the summer, and the air is very dry, he recommended 12 feet depth and 200 feet in length for the tile ditch.

To cause a draft, the outlet pipe was connected with a flue, and a gentle heat, by steam or other means, caused a draft in the flue. This draft was regulated by dampers. In order to warm cellars in the cold northern latitudes in winter, the conditions would require to be reversed, and a deep ditch made for the air-duct. Tile or stone was used for these tubes—flat stones for covering being preferred to tile.

The professor had also a patent for constructing a perfect horse-stable. He gave a great deal of attention to building stables and barns, with a view to warmth, pure air, and comfort. Certificates from the owners of dairy-rooms spoke very highly of his sub-earth system. Prof. Wilkinson supplied plans and specifications for sub-earth repositories, charging about $10.00, which is much better than to try to construct one by feeling the way by experimenting. If he is still living—he was in his 70's when I last corresponded with him—he could supply reliable information for the construction of sub-earth ventilators, with plans, cost, and all information required. My books were burned which contained the professor's address, but doubtless a letter would reach him, if still alive, directed to Brooklyn, N. Y.

Rising Sun, Md. E. E. EWING.

Many thanks, friend E., for your timely suggestions. My attention was first called to the matter of sub-earth ventilation by articles in the papers from Prof. Wilkinson. I afterward corresponded with him in regard to the matter, and he gave me a plan for a bee-cellar; but at the time I thought it too elaborate and too much machinery. You recall one item I had forgotten, and that is, that these sub-earth ducts can be used in the summer for keeping our rooms cool, as well as in winter for keeping them warm. Now the mystery to me is, why this matter has been dropped while such a wonderful field is open to us in the way of saving fuel by introducing air for ventilation, already raised to the temperature of the earth. If I remember, he recommended that the doors be made to shut as nearly air-tight as possible, that the windows be screwed down, and that all joints be made air-tight with putty. I am afraid, however, that during this beautiful May weather, when the balmy air just after a summer shower is being wafted in at the open doors and windows, it would be a pretty hard matter to induce people to keep the windows down, and sealed hermetically with putty, while air for ventilation came in only through long underground pipes. I still have very strong faith, however, that sub-earth ventilation may play a very important part in greenhouses—especially greenhouses having no heat except the heat of the earth and the heat of the sun. We should never need to open the ventilators in the roof, except when the heat of the sun is sufficient to demand letting some of the heated air out. This would start a current through the sub-earth tubes, and we could have a good current of air for a longer time without reducing the temperature as we do with the usual appliances. I should be glad to hear of any arrangements now in operation, made on the professor's plans, or to hear that he is still living and accessible.

PUTTING UP AND SHIPPING HONEY.

SOME EXCELLENT HINTS FROM A PAPER READ AT THE WESTERN BEE-KEEPERS' ASSOCIATION.

THIS branch of industry has grown, in the last few years, beyond the anticipation of the oldest apiarists. A few years ago our city and country trade was supplied by not more than a baker's dozen of our local bee-men, and they could not find sale for all they produced, without shipping it to distant markets, and waiting, perhaps, a whole season for their returns. For a man *then* to have shipped a carload of honey to Kansas City would have been suicidal to his finances. How different do we find it to-day! Kansas City makes ready disposition of all her home yield, in addition to large shipments from New York, Illinois, Michigan, Wisconsin, Iowa, Nebraska, Texas, North Carolina, Louisiana, Florida, and California. A reference to the *American Bee Journal* shows that Kansas City's quotations have been as high, or higher, than those of all other competing markets.

During the last season, we, as a firm, sold from 100,000 to 120,000 of 1-lb. sections of comb; from 90,000 to 100,000 lbs. of 2-lb. section comb, and 60,000 to 75,000 lbs. of extracted honey. Add to this, 50 per cent for the remainder of the trade, and we have the round figures of 225,000 lbs. of comb, and over 100,000 lbs. of extracted honey. These figures indicate that the "busy bee" must "improve each shining hour" more diligently to keep pace with Kansas City's love for honey.

Prices have ranged from 15 to 18 cents for 1-lb. sections; 11 to 16 cents for 2-lb. sections, and from 3 to 7 cents for extracted honey.

WHAT STYLE OF PACKAGE IS BEST ADAPTED FOR SHIPPING HONEY?

In commercial economy there is, to the producer, nothing of greater importance than the subject of transportation. In regard to the size, style, weight, and composition of packages and sections, there should be some uniformity of strength, and provision for easy examination of their contents. The most of the dealers are beginning to consider this point, for they discover that honey which is started to market as first class, may, on account of the packages, reach its destination as second class. The California producers have not yet adopted the 1-lb. section; hence most of the 2-lb. comb comes from California; but as they have already begun to agitate this matter, it will not be long before they adopt the 1-lb. frames, because they will discover that they can get more money for their honey. They use now exclusively 2-lb. frames; there being 24 frames to the case, and weighing in all about 60 pounds. We do not consider this a desirable size of package, but we would recommend the California package for extracted. It consists of a case containing two tin cans, each can having a screw top, and holding sixty pounds. This is far preferable to barrels or half-barrels. Dealers universally prefer it. Michigan, Wisconsin, and Iowa, use a very convenient size package for 1-lb. sections. If we remember correctly it contains 40 frames to the case, and weighs about 35 pounds net. The trade takes to this size of package as kindly as it does to smaller cases of 20 or 25 pounds.

We find that Missouri has a greater variety of packages than has any other State. We urge that your society exert its early and strongest influence to establish some uniformity in this direction. We suggest that, for one-pound frames, you pack two or three dozen in a case; and for two-pound frames, one or two dozen in a case—our preference in the latter instance being for one dozen in a case. We had so little call for the half-pound frames that we would recommend the abandoning of that size of section. Another suggestion, by way of improvement, is to mark plainly on every package the correct gross weight, tare and net, as well as the number of sections.

We can not, in this connection, refrain from referring to the highly important subject of the use of glass with honey packages. We have always insisted, and still affirm, that it is improper to glass every section. It does not take the consumer long to discover, when he is buying a pound section, that one quarter of it is glass. The consequence is, that you can not sell him many more such sections; and we suggest, therefore, that glass be used only in the front of each case.

In reference to the comparative merits of the different shipments of honey from different sections of the country, we will add that we have received consignments of extracted honey from North Carolina, Louisiana, Arkansas, and Texas. The finest-flavored honey came from North Carolina, and it was made from the huckleberry. It brought the highest price. The poorest honey came from Louisiana, and it was almost impossible to sell it; it looked and tasted more like molasses than honey.

PUTTING HONEY IN PROPER PACKAGES.

Now permit us to say a word respecting the preservation of honey, in taste or flavor. Some producers seem to think that all that is necessary is to preserve it in bulk—to see that none of it is lost. Now, the best of honey, like the proof of the pudding, is in the tasting. For illustration: We received a shipment of comb honey from Texas, which was made in water-buckets. The only virtue of this receptacle is, that the bees could have abundance of room for working in it. The bee had done his part, and brought to this "bucket-shop" of nature's choicest sweets, but the bee-keeper had deteriorated the honey just one-half its original worth by giving the bee an improper package in which to work. We suppose that he, with others, thought that Kansas City was such a "mushroom-opolis" of a market that, no matter what the quality of the honey might be, or the style of the package in which the honey was shipped, it would still command as high a price as his neighbor's honey which was shipped in a proper package. Let him take a lesson from the busy bee, and prepare his packages as thoroughly as the little insect worker makes his cells, and the honey will retain its natural flavor.

In regard to next season's crop, we have no direct information, except from California, which State promises a yield worthy the searchers after the Golden Fleece. This State has been blessed with an abundance of rain this season, which has made the valleys and hillsides bloom like the rose. A profusion of wild flowers encarpets the low grounds, while the mountain-sides are draped with an extraordinary growth of the white sage, which shrub constitutes three-fourths of the bees' supply. While those active insect-workers are improving each shining hour, let us put in our time with honest endeavors, both to preserve in perfection all the native qualities of this delightful product of dame Nature's delicate art, and to improve all the facilities for putting it in easy reach of the consumer.

CLEMONS, CLOON & CO.

Kansas City, Mo., May, 1886.

Friends C., C. & Co., we pronounce the above tiptop, and we take pleasure in laying it before our readers, even if it does savor a little of advertising your house. Our readers will find the package you recommend for shipping extracted honey, illustrated and described on page 274, April 1.

THE MATTER OF DISPOSING OF SEWAGE.

SOME SUGGESTIONS FROM ONE OF OUR ENGLISH FRIENDS, IN REGARD TO THE WAY THEY MANAGE IT.

I SEE in GLEANINGS that you ask your readers to let you hear what they know about the disposal of sewage. In England we have: 1. The earth system; 2. The precipitation system; 3. The water system.

The first of these is most applicable to country places: we have several in our small village. Instead of a wheelbarrow we use a tin pail and ashes, or dried earth, which the owner removes as suits him. The second system is mixing the sewage with chemicals in tanks. The water is discharged apparently clear, and the residue is mixed scavenger's refuse, which has been passed through a riddle, and the larger matter calcined. The third system is the flooding of land with sewage by gravitation or pumping. Cheltenham, a town of 42,000 inhabitants (10 miles from here) sends the whole of the sewage water to a distance of about 3 miles, over a face of 131 square miles. The houses, some 8000 in number, are generally provided with water-closets; it is conveyed, first, to tanks 44 yards by 10 yards by eight feet deep, in which, by a certain rough filtration, it is separated from its heavier mud, and the remainder flows onward to the land. The overflow is made to drive a turbine, by which the sludge is lifted above the level of the ground close by, where the house-ash, with other town refuse, wheeled by the scavenger-cart, is placed so as to receive it, and is doled out to the farmers at about 2 shillings per yard. Few of the sewage farms pay, I have heard, and then only on very light land.

I suppose you have heard we have had a long and bad winter for bees, and I hear of a good many losses. I believe we have over 10,000 bee-keepers, and our honey was down to 7 @ 8 pence, best comb.

ARTHUR W. LEATHAM.

Misarden, Cirencester, Eng., March 9, 1886.

Thanks, friend L. Since my articles on the subject quite a number of very ingenious plans have been submitted to me. Perhaps the best one in use, especially in large public buildings, is the plan adopted in the schools of Toledo, Ohio, and several other places. This plan is somewhat as follows: The buildings are warmed by hot air. The hot air, after having performed its office, is carried down beneath the water-closets (which in this case are closets without water), and this great volume of dried air is sufficient to take up and absorb all the moisture contained, so that the accumulations of several weeks, from a large school, may be carried away on a common wheelbarrow. This foul air, charged with dampness and gases, is set free from the top of a large shaft, or chimney, which carries it up so high in the air that its presence is never noticed in the neighborhood. I do not know just how the arrangement works in the summer time. Probably sufficient heat is maintained to keep the current of air passing up the large chimney. For towns and rural districts. I am inclined to think, however, that the plan I suggested is the cheapest and safest, especially when the owner of the premises has a little plat for plants and fruit.

DO BEES HEAR?

OR DO THEY FEEL THE VIBRATIONS?

ON page 305, Ernest says that queens do not "zeep, zeep," for their own pleasure. Why not? If a queen is "chock full" of happiness, what is to hinder her letting off a little of the pressure in the shape of an audible "zeep, zeep"? or if she is in a strange place, expecting every moment to be her last, with her heart rising up in her throat, as it were, wouldn't it relieve the nervous pressure, and perhaps save her life, to let off the "zeep, zeep"? Once I knew a boy. He was a bad boy. He went to a Fourth-of-July celebration, and he would climb trees. His mother and his two aunts and three sisters spent all the forenoon pulling him down by the feet; but while they were eating dinner he slipped away and climbed a tree, fell out of it, and broke his arm. The doctor came and set it then and there, the boy yelling, one heart-piercing yell after another, all the time. The women - folks promised him candy and peanuts, lemonade, and ice-cream if he would only hush; but the doctor said, "Let him yell all he wants to. It's good for him—relieves the nervous pressure." The boy was scared, all broken up, and the explosive sounds from his lungs eased him off and he soon went to sleep.

If bees feel things, vibrations of the air, and understand them, perhaps the zeep, zeep, causes a vibration that they feel and understand.

Years ago, on the last day of school we had a picnic. All the children, with baskets and buckets and bouquets, marched out to the woods to eat dinner. Among the children, laughing and running, was a deaf girl; she could not hear the least sound; but in addition to her laugh she uttered a shrill sound that sounded more like a horse in pain than any thing I can think of. She was having a splendid time; but the sound she made from time to time did not tell the story. Another time, on our way home from church we stopped a few minutes when she and her sisters were swinging; and while we talked with one sister the other swung the deaf girl; and each time, as the swing went up, the deaf girl uttered that piercing sound; this time it was fear, but it had exactly the same sound as her notes of gladness at the picnic. It puzzled me, that the sound to express joy and that for fear should be the same, and I resolved to find out if all deaf persons make the same sounds, but have never had opportunity to do so. This girl afterward married, and lived within about 20 rods of the railroad. She had two little girls, and they were always playing about, sometimes on the railroad. I worried over the matter for years, and often thought I would stop and ask her to watch the children, but I was not very well acquainted. Finally I did ask her if she was not afraid to let the children play on the railroad.

"No," said she, "I always know when the train is coming—I feel it, and I look out for them." She was not born deaf and dumb, but lost her hearing from scarlet fever when about a year old, before she had learned to talk.

As to the queen piping to call out the swarm, I thought we were taught that the queen did not manage the swarming; and if her piping means joy or fright, perhaps she felt the excitement that was all through the hive, and gave voice to it. Who knows? MAHALA B. CHADDOCK.

Vermont, Illinois.

Mrs. C., you have certainly given us some new ideas on the subject, and there is no doubt but that you are right. The deaf girl knew how to utter only one sound, so she used that sound on all occasions. She was something like the amateur fiddler, who explained to his audience that he knew only one tune, and therefore he always played that first. Strange, wasn't it? Well, now, may be it is the same way with the queen and her "zeep, zeep, zeep."

DO BEES HEAR? — SOMETHING FURTHER.

You say that bees can hear a queen if she is on a frame held at some distance from a frame with other bees. Can they hear if one frame is on the ground, and the other in your hand? or do they, when they make a piping, jar the comb enough so it will telephone the jar to the other bees? I tried it in this way: I fed them a teaspoonful of honey at the entrance every night this spring; at the same time I hit the spoon on the bottom-board (mine are portico hives), and they always came out at the signal, and it would start them buzzing if I rubbed my finger lightly on the hive. I then took a bell and rang it when I fed. I practiced this with my 40 colonies every night for some time, always hitting the hive in some way before they would start. Now, if they hear, why wouldn't they take the bell as a signal without my first jarring them? J. L. HYDE.

Pomfret Landing, Conn., May 10, 1886.

STARTING BEES INTO SECTIONS.

CAN HYBRIDS BE HANDLED AS EASILY AS ITALIANS, IF MANAGED RIGHTLY?

A BEE-KEEPER said to me last spring, "Why do you let your bees swarm, if you want honey and not an increase?"

I answered, "If I knew how to prevent it I would never have them swarm."

He answered, "Keep them busy—too busy to swarm."

I took the frames out last season as soon as they were filled. I had one swarm. This season I have not had a swarm so far. Six colonies are just filling sections right along, as fast as I ever saw them filled. I had some trouble to get two colonies to go up into the sections, but I put a frame of brood in the upper story, and they commenced next day to store in those next to the brood. Now they are all six at it.

I have seen so much about cross hybrids, that from the first I anticipated much trouble with them. I have never had a cross colony. I do not know why; but I often go through a hive, lifting out every frame, and never use a smoker. Sometimes they show a little disposition to fight; but a puff or so of smoke subdues them. I have never owned a cross colony. Can you tell why? You said, some time back, that in the fall, when honey was scarce, they would fight fearfully. Last fall I had to examine them to find out if they had enough to winter on. I took from some and supplied others, and they were as quiet as at any other time. Once my little boy set a frame of unsealed honey down that I had given him to take into the house, and they commenced to rob; but I closed every entrance so as to admit only about one bee at a time, and next day things were as quiet as usual.

JEHU G. POSTELL.

Orangeburg, Orangeburg Co., S. C., May 7, 1886.

I am inclined to think, friend P., that you may not always be as successful as you have been in having gentle bees, although very much depends on the way bees are handled. If you do not get hold of a colony pretty soon that takes the conceit out of you, then I shall be somewhat mistaken, especially if you run your numbers up into the forties and fifties.

SOMETHING FROM OUR GOOD FRIEND CYULA LINSWIK.

HOW HER BEES WINTERED THIS YEAR.

"FOR he on honey-dew hath fed,
And drunk the milk of Paradise."

These lines from Coleridge, slightly changed, as thus—

Since they on honey-dew have fed,
They sip the sweets of Paradise,

We have chosen as an appropriate and suggestive epitaph for eighteen colonies of Italian bees now sporting in the Elysian fields. They died during the past winter and spring; each snugly packed in chaff on its summer stand. Forty-four colonies remain to us. A large majority of these are good; the remainder considerably below the average standard for this locality at this date, May 10.

Intimations in late numbers of GLEANINGS, that the wintering problem is growing unseasonable, forbid my telling the story in detail, impossible as it might be to refrain from adding thereto inference, speculation, and opinion. But we have received, in days past, too much credit for our success with outdoor wintering—shall I say our good fortune, rather?—to avoid this brief public confession of failure.

We doubt not that the friends with whom we oft have mourned will rejoice to sympathize with us. Nor will any one of them, surely, be cruel enough to say, "I told you so!" CYULA LINSWIK.

Very likely the honey-dew which the poets wrote about in olden time was different from the kind we have nowadays, friend Cyula; or perhaps they didn't have any honey-dew at all, and talked about something nobody knew any thing about, as we sometimes do, even in this latter age.—Now, I am not glad that you and your sister have had a little experience in winter losses, but I am glad that you come out so promptly and own up. I have sometimes been forced to conclude that it was more good fortune than good management; but you see you did not feed them on sugar syrup. May be, now, you will be more ready to agree with friend Heddon and myself.—It is true we have been obliged to pass by a good many reports in regard to wintering; but we have never felt like passing by any thing from you or your sister, therefore we want you to remember that there are exceptions to this rule as well as to almost all rules; and when you feel *prompted* to write any thing, don't repress the inclination, but let us have it.

A STRANGE FACT IN REGARD TO QUEEN-BEES.

A FACT THAT IS ALSO OF CONSIDERABLE IMPORTANCE.

I WONDER if others have queens faint away and come to again, as some of ours have done. Last summer, in looking for a queen we could not find her in the hive; but when about closing up I saw her lying quietly on the alighting-board, where some of the combs had been set. I picked her up in my hand, and she appeared dead—no life at all. My first thought was of tossing her away; but the next thought was to drop her in the hive among the bees. I did so, and in a week I examined the hive and she was laying all right, but showed signs of a little weakness. She was a young queen, fertile only ten days or so, but she has not kept her hive so well filled with brood as some others, and now she is but one year old. I think I shall give the colony a more vigorous queen.

About five years ago, on looking through a hive for a queen I could not find her. I looked on the bottom-board, and there she was, apparently dead. I took her up in my hand; and as I wanted to save a dead queen to show to visitors, I told the attendant to lay her on a big box a rod away, until I went into the house. What was my astonishment, when, on going for my dead queen, to find her surrounded with two or three dozen of her own bees (I suppose), all doing homage to her, their heads mostly all turned toward her, and caressing her with their antennæ. I put her back in the hive and she was, to all appearance, a well queen for a year or more.

Again, in swarming time my wife caught a queen in a cage with a few bees, and laid them in the sun, intending to take care of her soon, but forgot her for two hours or so; when found she was apparently dead. I placed her in a hive, and she revived and lived to do good service.

One fall, after uniting several nuclei, we forgot a queen and a few bees we had hunted out and did not care to save, but disliked to kill her, so we put her in a cage and laid it on the ground, intending to put her on top of brood-frames in some colony, thinking possibly we might find a hive queenless. She lay out all that night; we had a hard white frost, and next morning I found that she and all the bees would shake round in the cage as if dead. I put the cage on top of a colony of bees for a day or so, and on going to it all were as lively, apparently, as if nothing had happened.

Our bees have wintered very finely indeed; those outdoors are at this date at least one-third stronger than those wintered in the cellar. All were packed in straw, but they were one-third stronger and better colonies last fall. We had several nuclei quite weak last fall. We crowded the bees on to two well-filled combs, and packed with straw all around, and put in the cellar. They all wintered, and to-day bid fair to make fine colonies in a month or so.

The spring seems very forward. Apple-trees bloomed two weeks or more earlier than last year.

I think Mr. Heddon's book well worth the money. There are some very practical suggestions in it. I disagree with him, however, in regard to women and invalids keeping bees. I think a few colonies just the right stimulus for invalids—better than alcohol or wine; and as for ladies, I wonder how many successful men there are in the business without the help and co-operation of some woman, either wife, daughter, or sister. L. C. AXTELL.

Roseville, Ill., May 12, 1886.

Friend A., you may remember this subject has been up before. From your description I should think you had met with suspended animation, occurring from two or more causes. My first experience in the matter was when buying queens some years ago of a neighbor. All of a sudden a queen we had caught doubled herself up as if she had been stung, and was apparently lifeless. I thought her dead, but he said he had often seen them do that, and that she would come out all right if we would put her among the bees and let her alone. Sure enough, when the hive was opened, an hour afterward, she seemed as well and natural as ever. I have since seen it several times, especially when picking queens off from the combs to send them away; they seem knotted up as if in a cramp, and I doubt not that many queens have been thrown away for dead when it was only this feature of suspended animation. The case you mention, where queens were found on the bottom of the hive, can not be so easily explained. I had supposed it was caused only by fright or improper handling. I have often seen queens and bees, apparently dead in their cages, from the effects of cold, and nothing else. I have also seen queens, when left away from the bees, frozen until the frost was plainly visible on their bodies; but in every case where they revived when warmed up, they laid worker-eggs just as well as usual, so far as we could see.—I agree with you in your concluding remarks in regard to bee-keeping for women.

LAWNS AND LAWN-MAKING.

SOME PRACTICAL EXPERIENCE IN THE MATTER FROM FRIEND TERRY, THE POTATO-MAN.

FRIEND ROOT:—You did a nice thing when you hunted up a simple, cheap lawn-mower to sell to your readers. I have no doubt there will be more pretty lawns where GLEANINGS goes, as the result. And what is more beautiful than a smooth green lawn? Why do we not see more of them in the country? It is not a very difficult matter to grade the ground and sow the seed; nor is it a hard job to run the lawn-mower over the yard once a week or so. Any man with half an eye for beauty would feel amply paid for the trouble, by the beautiful, even coat of green that would result. And then it is so nice for the wife and daughters, when they hang out the clothes, on washing-day, or when they are tending to their flower-beds.

Possibly the writer's experience might help some who are thinking about a lawn. Our yard was very uneven and rough when we came here—an old farm-yard. We did not attempt to make a lawn until we had a new house built, as the digging of a new cellar would spoil it all; but we set out trees, hedges, etc., with reference to future grading. A year ago this spring we began on the yard by spading it all over deeply. Then, every few days, all summer, we went over it with the Acme harrow, and hoed around the trees where we couldn't get with the harrow. Where there were hollows we drew in dirt, and where it was too high we took off a little. In this way by fall we had it pretty well graded, and the horseradish, tansy, and numerous other such plants as those found in all old farmyards, thoroughly disposed of. About the last of August we fixed it up as smooth and nice as possible, and sowed on blue-grass seed and timothy, some four or five times as much as we would on the same amount of ground in the field. Then we rolled it by hand with a part of our field-roller fixed up for the occasion. Next, boards were laid down to walk on, where we were intending to have paths in the future. No manure was used, although some fine rotten compost would have been an advantage; but we did not have any. The seed came up finely, and the lawn was quite green by winter. We let it grow this spring until it was, the best of it, some eight inches high. Then we mowed it over with a scythe, and, after the next rain, rolled it, and soon began using the little lawn-mower we got of you. We have been over it twice already (May 20), and have got a pretty fair-looking lawn, for a young one. It will probably be best not to cut it very much more this first season, unless it is very wet. At all events, it should be allowed to grow up in the fall. Of course, the most of the show now comes from the timothy; but the blue grass is growing, and will make a heavy sod in time, and displace the timothy. No such lawn could have been got the first season from the blue grass alone, although in time that will be all that is needed to make a splendid turf.

Lately we have been making roads and paths; for one good thing, you see, leads to another. We took the boards all up that we had been walking on during the winter, and cut out about five inches of soil, and then drew in gravel and filled up. Of course, some pains were taken to lay out the road and paths so as not to have them look stiff, and so they would be as convenient as possible. It took about 80 tons of gravel, and was quite a job; but it is a permanent improvement, and it did not cost a cent, only a little hard work when we could spare the time from our regular farm duties. We can drive into the yard and by the coal-window, and the wood-shed door, and the cellar-door, and also the cellar-window, where we put in potatoes in bulk, and on out of the yard, and not have a horse step off from the gravel road. When our new barn is built, the road will be extended to that, and then we shall be out of the mud, as we intend to cover the barn-yard.

Now, friend Root, you ought to get a heavy lawn-roller to sell us, to keep the road and the walks and lawn rolled down smooth. There are some other matters pertaining to the territory inside of the dooryard fence that I should like to write to you about at a future time, but meanwhile I hope many readers of GLEANINGS will invest a little *work* in their dooryards in the way of lawns and dry walks.

Hudson, Ohio. T. B. TERRY.

Very good, friend T. But when I get a lawn-roller, something else will come up, and where will the end be of the things I keep for sale? A good roller would be a pretty heavy thing to ship. One of the best I have ever seen was cut out at the stone-quarries, like a small grindstone, for it was about 2½ feet thick. With a suitable frame, one horse would draw it nicely between rows of vegetables, or anywhere else you wanted lumps mashed up or ground compressed. After setting out celery-plants, it was an excellent thing to pack the dirt around the young plants; but it was so heavy that, if you didn't look out, on a steep side hill it might throw the horse over. Ours was burned at the time our warehouse was destroyed. I presume many of the friends could have them made at the stone-quarries near them. I suppose the next best thing would be a cast-iron one. I am told the stone ones can be had at the quarries, where grindstones are made, for about $2.50 for the roller alone. By all means give us something more in regard to the territory inside of the dooryard fence. If it is true, that, "as the twig is bent the tree's inclined," how much may so simple a thing as the dooryard have to do in shaping the future lives of our boys and girls!

APIS INDICA.

Their Good and Bad Traits, Carefully Considered by our old Friend Bunker.

THE TERRIBLE RAVAGES OF MOTH.

I HAVE now experimented with *A. Indica* one full year, and report. If profit in honey and wax had been our aim, you would have to put us in "Blasted Hopes" in short order, surely; but as knowledge of this new race of bees has been our aim, we are safe for this year. Experiments were begun in October last year, when our first swarm was secured. By natural increase, and by addition of wild swarms from time to time, our number of swarms increased to nine in August last. Two swarms are now left, and one of these has swarmed out twice; but now, however, it seems to be inclined to remain with us. The first of these two is very large. There must be a full peck measure of bees. It is a swarm from a domesticated wild swarm. The other seven swarms have all taken wing for the woods, together with several first casts, which we failed to secure, either because they did not alight before leaving for the jungle, or other reasons.

I will not weary you with daily or monthly reports, but will give you results as briefly as possible.

1. The reason why these swarms have left (others than natural casts), seems to be wholly due to moths. When the hot weather of the rains began, I noticed signs of moths, as given in the A B C. I found old combs being torn down by the bees, and worms on the bottom-board. This board was carefully swept every few days, and worms killed. Occasionally I found them under the cloth on the frames, and from these evidences I was persuaded that the bees were making a good fight of it, and would be able to take care of themselves; and as some of the combs being torn down had brood, I delayed removing them; also being very busy with my mission duties I did not examine all the combs as I should have done. As a result, the bees began to swarm out; and on looking over the combs I found them full of worms. One large swarm, from some reason, hastened queen-rearing, and, without waiting for drones, swarmed twice, and finally the whole left. One of these swarms was captured and kept for a little while with what I thought to be a clean frame of brood; but as soon as the brood was hatched out, the bees left, and I found moths in their comb.

Now the war began, myself and bees on one side, and the moths on the other, and the moths won the day. I followed up each hive and gradually withdrew all comb showing moths; but I was not fast enough, and swarm after swarm absconded. I found that every place where there was a collection of wax from fastening the combs in transferring, there was a nest of moths, and that the moth-worms had even burrowed into the pine wood, and thus were safe from the bees. These worms multiplied with great rapidity, and ate their way rapidly through the combs, covering their tunnels with a strong web. But in no case did they trouble *new* comb. They seemed to be after the cocoons left by the hatching of young bees, and not for wax alone. I conclude, therefore, that my mistake was in not cutting out all old comb at the beginning of the rains. Again, as the *A. Indica* deposits *no propolis whatever*, the hives must be made carefully, and the frames for comb should be of such material that moth-worms can not eat into it.

2. Besides the moth as an enemy, there are others also destructive, as a variety of lizards, from two to six inches long, house frogs, small sparrows, and ants. The smaller lizards seem to be privileged characters. I have seen them dash through a squad of fanning bees, into the hive, without a sting. Cockroaches are often found in the hives, and I have seen them run down on the combs, and the bees only make way for them.

3. These bees are not large comb-builders or honey-gatherers. Under the most favorable circumstances, 30 lbs. of honey a year from a swarm would be a rare event. They seem to bend their energies on brood-rearing, and make comb for that purpose, and not for storing honey. I do not think they can be led to take to supers at all. If supers with full combs were supplied a swarm, they might be induced to store honey in them during the best season, but they will not build comb for storage. Their enemies are so many, and the moth so destructive, they strive to raise as much brood as possible through the breeding season, and then leave for new homes, and begin anew.

4. Hence the bee-year is divided into two seasons, like the climate—first, from December to June, and from June to December, six months each. Only in rare cases will the bees occupy the same home the year round, in their natural state. Even if their combs are free from moth, it seems to have become natural for this bee to swarm out at the end of each bee-season and seek a new home. With knowledge and care this tendency can be wholly overcome, I believe. From books about bees in cold coun-

tries, I was led to suppose that here, also, old combs would be desirable as a saving in bee labor; but combs more than six months old, even if not attacked by moths, become brittle, and the bees do not like them. Old combs introduced into the center of full swarms, though perfect, are often shunned by the queen, and used, if at all, for storing honey. So, then, we conclude that *A. Indica* is very particular, and likes only new houses; and, rather than live in an old one, will take to camping out.

One swarm, which I had succeeded in keeping the year round, and from which I got 8 lbs. of honey, finally became so dissatisfied that they swarmed out and left the queen, whose wings had been clipped six months before, on the alighting-board; and though they clustered a few rods away, they would not come back. They could not have had another queen, as they had neither queen-cells nor drones in the hive.

5. Although there are shrubs and trees in bloom all the year round, yet the honey-season seems to be from February to July inclusive. It seems that bees migrate in the midst of the honey-season, which appears to be the fact. From February to the last of May is decidedly the best of the season. As the time for migrating approaches, the queen ceases to lay eggs; and when the brood is hatched the honey is consumed, and the bees seek a new home, and set about a new house with much energy. In thus migrating during the honey-season, the bees secure a new home and supplies for the next six months. At the beginning of the rains the swarms are very large for this bee; but at the time of migrating, in December, they are much reduced. It must be noted as a curious fact, that, after spending one season away, they will often very regularly return to their old quarters, so that certain "bee-trees" come to have value as a matter of property among the natives, on account of this curious fact.

6. In experience, many queens are lost on their wedding-flight. Scores of sparrows are watching for them; and as their flight is heavy, they are easily caught. In uniting bees, for instance a swarm without a queen with a swarm having a queen, care must be taken, or the queen will soon be found dead outside, though otherwise they dwell together peaceably enough. I united two queenless swarms once, proposing to give them eggs to make a queen for themselves, and they lived together several days very peaceably and then swarmed out, one swarm taking the right and the other the left road to new quarters. Fertile workers are met with here as among European bees. One queenless swarm tried to make a queen of a drone.

7. These bees are extremely gentle. They will seldom attack, save when the hive is full of honey and brood, and then a puff of smoke is quite enough to send them on their knees. They fly about, alighting on the face and hands, with a plaintive buzz, which says very plainly, "Please," and we understand the rest they would say if they could speak. How clearly they say "come" to each other, when they find a new hive, or the swarm from which they have been separated! Speaking of their gentle disposition, I have often watched a squad of these bees make a combined attack on a big green fly, which often persistently troubles them. By a rush they rout the fly, yet he soon returns and settles near some bee, who quickly takes to her heels, as if a terrible enemy had come. They very readily run off the combs on to the top-bar or hands, in handling; though if the hands be smoked a little first they shun them. Notwithstanding their gentleness they are great free-booters and attack each others' hives mercilessly. In these battles they soon cover the ground about the hives with the dead.

8. They will not run into a hive when poured down in front of it, but take flight. They take possession of a hive when one wants them to, very reluctantly; but a bit of brood, sealed or unsealed, fixes them at once. If handled too much, the queen stops laying, and after the brood is all hatched the swarm absconds.

The above are some of the results of a year's study of these bees, the *A. Indica*. A second year's study and experimenting is likely to modify some of the above observations. Only after repeated experiments will it be wise to lay down rules. These bees are not likely to become profitable property, though one can not say what will be the result, if crossed with other breeds. There are at least three species of *A. Indica*. Their relative merits we can not yet pronounce upon. Further experiment is necessary.

Toungoo, Burmah, Dec. 1, 1885. A. BUNKER.

A LITTLE ADVICE TO LOCAL SUPPLY-DEALERS.

LACK OF JUDGMENT VERSUS WILLFUL DISHONESTY.

THERE are but few who realize how easy it is, in the course of circumstances, for a perfectly honest man to start out with nothing but honest intentions, and in a short space of time be condemned as a dishonest man. These few lines are directed mainly to bee keepers, still they will apply to many other branches of business. Bee culture of our day, under its great progress, requires, to carry it on profitably, many implements and supplies, not easily manufactured on a small scale in every bee-keeper's home. For this reason it becomes necessary that there be manufacturing establishments where such goods as are required by bee-keepers can be made. Now, the bee-keepers are so thinly scattered over our great country that such establishments are necessarily situated some distance apart. This has caused heavy expense in expressing small amounts of goods great distances, and it is this very thing that has led to the trouble I am about to speak of.

In almost all localities there is some one more interested than others who reads up, sends and gets foundation, sections, smokers, etc., transfers his hives, and commences the business under modern management. His more backward neighbors begin to get interested, and, of course, look to him for assistance. They want him to send for supplies for them; and, partly to accommodate and partly that he can add this supply department to his business, he at once applies to some supply-dealer for terms to sell again; and, as all supply-dealers know, these applications come, not by tens, but hundreds. He gets rates which give him a fair profit, by having his goods shipped by freight in quantities. He has no hundreds of dollars to put into the business, but is an honest man, and the dealer gives him credit. He commences selling to his friends and acquaintances; he has got credit, so he sells to his friends, and gives them credit. Time passes on. He perhaps takes one-third cash, and turns that in; the season ends; he is notified by the dealer to pay up, for he wishes to prepare for another season's trade. He begins to try to collect, and, to his surprise, is very much disappointed; he finds it harder to collect these little bills than he expected. He finally looks the matter squarely in the face, and at once decides these bills must be collected, for he has no other way to pay; so he sets himself about it, gets many of his friends mad at him, and at last finds himself with a large bill against him, unable to pay it, his credit gone, his honesty condemned, all because his friends thought he could wait on them; that he had no occasion to press them for the few dollars they owed him. So it turns the man, started with nothing but the purest of motives, but at last he is held up as dishonest.

Now, my friends, this picture is not overdrawn, as not a few can testify. Much the best way is to pay as you go, and be happy; for then one's mind is free and easy; but on no account buy goods unless you know where the pay is coming from; and never buy goods on credit to sell on credit again; in other words, never trust out another man's property.
J. B. MASON.

Mechanic Falls, Me.

Friend M., your picture is a truthful one, I grant; but it applies to other kinds of business as well as to the supply-business in bees, etc. Whoever commences in business of any kind should remember that he is assuming responsibilities; and when he begins to trust out the stuff, whether he pays cash or buys on time, he is assuming heavy responsibilities. If he is inexperienced, by all means his better way would be to do a cash business, as you recommend. As he gains, by experience, knowledge of men and things, he can begin to accommodate men who are universally recognized to be safe. There are a good many reasons why it is convenient to have accounts with good customers. It is a great saving of freight by getting some goods, oftentimes, before you really want them, because then you can have your goods all come together. Another thing, it is inconvenient to remit small sums; and where one has a credit he can order by postal card with much less trouble than where he has to send the exact sum of money every time. Now, then, comes the point of deciding whom he can trust and whom he can not trust. I have found this a very good rule: Grant credit for small amounts to those whom you have every reason to believe are able and willing to do all they agree to do; but just as soon as you find a man who says, "I can not pay now, and you have got to wait," square up with him as quickly as you can, without making unnecessary trouble, and then tell him plainly but kindly that you can not give him more credit. Where a man writes first, and asks if you can possibly give him a little more time, mark him on your books as all right, and worthy of confidence; but those who take time, whether you grant the privilege or not, are not entitled to credit, in my opinion. In this way you teach those with whom you have deal to carefully guard their reputation and business standing. Any one who takes offense because you think best to refuse credit, has shown himself by this act to be unworthy of credit. It is every man's privilege to demand cash for his goods or produce, if he chooses to, and no *good* man will be offended if he chooses to exercise this privilege. A great many beginners in the supply-business get into trouble because they push ahead heedlessly; and such people will get into trouble in any kind of business if they succeed in getting credit at all.

* * *

VIALLON'S PLAN OF SECURING SURPLUS HONEY IN 1-LB. SECTIONS.

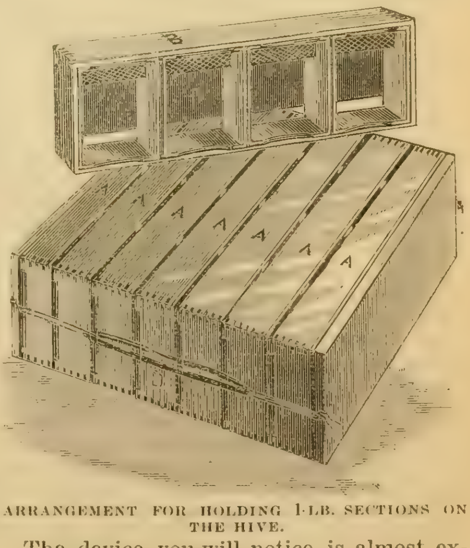
SOMETHING WHICH HE CALLS THE DOOLITTLE SURPLUS ARRANGEMENT.

THERE seems to be no end to the plans and devices suggested and used for holding sections with separators so as to place them on the hive without much trouble, and still have them convenient of access, and convenient to ship. Friend Viallon writes as follows:

We use for comb honey 7 wide frames clamped together as per Doolittle's plan (see *A. B. J.*, March 10, 1886, page 149), open top and bottom, dovetailed at corners, holding 4 Simplicity sections and separators clamped together with the thin outside boards. I have corresponded with friend Doolittle about it, and have agreed to call it the Doolittle surplus arrangement for comb honey. I have used such a frame with better results and more satisfaction than the two tiers of wide frames; as these have no projections to hang on rabbets, I lay the 7 frames, when clamped, on a perforated zinc board, and put a regular top story of Simplicity hive over. Two or more tiers of these frames can be used, if necessary. These wide frames are made a trifle over 1⅞, so that they when clamped press all the sections together, and, when placed on the perforated zinc, no bees can pass outside of these frames, etc. I intend to advertise and manufacture these in preference to any other.
P. L. VIALLON.

Bayou Goula, La., May 1, 1886.

We submit an engraving of the surplus arrangement, as figured below.



ARRANGEMENT FOR HOLDING 1-LB. SECTIONS ON THE HIVE.

The device, you will notice, is almost exactly, if not quite, the same as our three-box case, which we have advertised so many years. To fasten these together, friend Viallon uses a couple of wires with a stout rubber cord to draw the side-boards close together, and to keep every thing tight. Such an arrangement works nicely on hives, but it is not practicable to use it for shipping honey to markets. For home use, however, it seems to answer every purpose.

HEADS OF GRAIN
FROM DIFFERENT FIELDS.

OILED CLOTH IN PLACE OF GLASS, FOR HOT-BED SASHES, ETC.

IN reading GLEANINGS for Feb. 15, 1886, pages 141 and 142, etc., I should like to say that Mr. Henderson's ideas of using cloth well oiled, in place of glassed sash, is *good*. I have practiced it for years. I make a frame, something as you do, to put in glass, but tightly draw the cloth across and tack down close. These handle nicely. I alternate these with glassed sashes, every other section (or sash) being cloth. They can be changed occasionally, placing the cloth sashes over where the glass sashes have been, and vice versa.

Like you, this sort of work fascinates me, and truly it's a great pleasure to watch your plants, which seem to grow under your eye, while all is cold beneath, and desolate outside. Another thing, we must realize that it is profitable as well. I have watched you all through this "hobby of yours;" have seen you err, and smiled, but knew you would eventually "get there," and I must truthfully say you are fast doing so now, to judge from your writings. Long may you live to enjoy the "new horticulture, etc.," is my prayer. R. C. TAYLOR
(Formerly of Wilmington, N. C.).
Fort Scott, Kan., April 8, 1886.

WHAT MADE THE BEES SWARM SO?

Can you tell me what ails my bees? My first swarm came out March 7. I hived them in a new Simplicity hive, which they seemed to like very well; but after remaining two days they swarmed out; and as the queen was not able to fly I caught her and put her back in the parent hive where the bees all went. Next day they all swarmed again, and I hived them in a new Simplicity; but not the one I put them in first. They remained in that three days, and swarmed out again, and took French leave. My next swarm, a week later, acted a good deal the same way, only they left the same day, after being hived twice. The third swarm, which was about a week later still, went off without being hived at all, and I have had no swarms since, though I have 20 colonies, all apparently in good condition. Now, as I know but little about bees, will you be so kind as to tell me the cause of their acting in that strange way? Bees seem to be gathering some honey now from the rattan and grape blooms. I sowed my buckwheat April 20, and I see some blossoms on it to-day, just twenty days from the time of planting. J. W. THOMAS.
Tehuacana, Texas, May 10, 1886.

I think, friend T., that your bees had a sort of swarming mania. Sometimes it seems to run in a particular strain of bees. They get swarming on the brain, and they swarm anyhow, no matter how you fix them, nor what sort of a hive they are put in. I should assuredly have given them the frame of unsealed brood, recommended so much. If you have any more such work, suppose you try it.

ARE YOUNG BEES OF THE BLACK RACE SUBJECT TO CHANGE IN COLOR?

I have four stands of the native, or wild bees; they have a hazel-colored body, and are black at the extremity of the abdomen. On the 14th of April I hived a swarm and noticed that there was a part of the bees of an orange color. Thinking they were young ones, I did not take notice of them so much; but as they continue the same color yet, I should like some one to explain, if possible, the cause of said change, as none of my old bees are so.
Blackville, S. C., April 20, 1886. D. D. SLATER.

Young bees of any race are lighter in color, because of the peculiar down, or fur, that covers their bodies. As they get older this fur gets soiled, or wears off, and they look dark, or sometimes almost black, when contrasted with the young bees that are for the first time taking wing. I do not know of any other way in which bees change color.

IS BEE-STING POISON GOOD FOR CROUP?

I see you publish what honey is good for to restore health. I will just say for your readers that 2, 3, 4, 5, or 6 honey-bees, or 1, 2, 3, or 4 bumble-bees (according to age of patient) steeped in water, say about ½ to 1 oz., and sweeten to be palatable, is almost an infallible cure for croup, and produces a pleasant sensation in the throat or stomach instead, of the sickening sensation usually resulting from medicine given by doctors or our grandmothers for croup. It only needs to be tried by yourself or any one to fully appreciate its pleasant taste. This remedy is well worth any one's trial. I think the relief comes from the poison of the sting. I also know the same to be good for a cold on the lungs.
Memphis, Tenn. JAS. F. WRIGHT.

If the poison from the sting of the bees were in sufficient quantity, it would probably produce sickness at the stomach, just as lobelia and other similar drugs do; and this would, without question, relieve the croup. Why it should give relief to the croup, without producing any nausea, is something I can not answer. Very likely, however, it may act as a remedy. It is certainly sufficiently powerful to act instantly, and this is just what is wanted with so acute a disease as the croup. Mr. House told us, some time ago, about the number of sacks of bee-stings he was selling to the medical fraternity. Now, have these friends who buy the poison-sacks been aware of the curative properties of this remedy for croup and similar diseases?

WHAT AILS MY BEES?

My bees are dying with plenty of honey in hive. I am afraid they have some disease among them. Have you any remedy to prevent disease among bees? or what do you think is the matter with them? I have your A B C. T. W. MOORHEAD.
Fairview, Pa., May 10, 1886.

It is quite unusual for bees to die during the month of May, with honey in the hive. I can think of no explanation, unless it is that their stores are poisonous, for some reason or other. I do not know of any disease that would make the bees die at such a time and under such circumstances.

SUCCESS IN THE HILTON CHAFF HIVE; TROUT-RAISING.

My bees pulled through the winter in good shape —40 colonies in the Hilton hive, and 6 in other chaff hives. I did not lose a single one that was in the Hilton hive, but lost five out of the six in the other hives. For practicability and efficiency, Hilton's hive is hard to beat.—I have just turned off my first crop of trout, nearly 400 lbs. I obtained 50 cents per lb. Next year will be interesting, and I shall have ten times as many. I will say to friend Milton P. Peirce, that the temperature of the water has more to do with the quality of domestic trout than the food that is given them. W. D. French.

Grand Rapids, Mich., May 12, 1886.

PROSPECTS FOR BEE-KEEPING IN SAN DIEGO, CAL. "BUG SHEPHERDS."

I have come to California for my health; and being anxious to do something to keep busy, and make some money, I naturally think of bee-keeping, having kept bees in an amateur way in the east, where other business occupied most of my time.

I find, on looking over the business here, that there are fine opportunities in this county, and plenty of scope for improvement over the present system of bee-keeping in vogue here. All the comb honey here is in 2-lb. sections, and but little foundation is used; the top-bar of sections being three-cornered, the comb is usually pretty true.

Now, my object in writing you is to obtain your views concerning the proper size of brood-frames for lower part of hives in this climate, making the upper story adapted for 1-lb. sections. The thermometer seldom goes as low as 32°, at least in the country not over 25 miles from the coast. Some bee-keepers ("bug-shepherds" they are called here) talk of double or air-spaced hives; for in some places the thermometer reaches 110° in the shade, and one man told me that it would not answer to have the hives stand in the shade. I think that, if the bee-keepers here can be persuaded to use 1-lb. sections and fdn., there would be a fine opening for sale and manufacture of material here. F. P. Miles.

San Diego, California, March 25, 1886.

Friend M., the proper size of brood-frames you will find in our price list: and for a full discussion of frames and hives, see our A B C book. As we find the chaff hive much the best here in our climate for extremely hot weather, I think you would find the same thing, or something similar, just what you want in California. By all means put your hives in the shade during the hottest part of the day or the hottest part of the year. The shade of trees will generally best accomplish both purposes.

ABSCONDING IN FRUIT-BLOOM; WAS IT CAUSED BY THE ABSENCE OF A QUEEN?

Will some of you veteran bee-keepers please explain why this is? A neighbor of mine had a swarm of bees come off about the 10th of April. He followed them some distance until they settled; but before he could secure them they decamped. Now, as it was only the beginning of fruit-bloom, and no honey coming in, I tried to persuade him they were probably starved out. He said, "No, they left honey, but no brood." To convince myself he was not mistaken, I went and examined the stock, and found them as he had stated, and about a pint of bees, but no brood nor drones.

As far as heard from in this locality, the bees wintered nicely; hardly any loss. Mine all came through well, and to-day I had a swarm—the first one I ever knew so early in the season.

Oxford, O., May 3, 1886. John Coulter, Sr.

Friend C., the department headed "Absconding," in our A B C book, discusses fully cases similar to yours. Absconding during fruit-bloom is usually caused by scarcity of stores; but in the case you mention I should say the colony had been a long time queenless, and the remaining bees, doubtless comprehending the ruin that lay before them, absconded, thinking they could join some other swarm somewhere; or, perhaps, they left without knowing what they could do, thinking they couldn't make matters worse any way.

GOT THE BEE-FEVER BAD; WHAT IS THE REMEDY?

You prescribed the remedy, and now I call on you to prescribe the cure. But, hold! methinks I hear you ask what all this tirade is about. Well, let me explain. Two of our most successful farmers have thrown down the plow, and have taken up that terrible weapon, the bee-smoker, instead. One of our flourishing merchant princes has cracked the yard-stick, and has gone to flourishing the same weapon. One of the best mechanics in the neighborhood has got bees bad; and it is reported now that another of the best farmers in the community has got bees so bad that he is going to stop and let his plantation wash away while he goes into the bee-business. Now, Mr. Root, we have made a plain statement of that much of our grievous causes, but that is not all. You may go to the country store, and it is bees from daylight until dark. Go where you please, it is bees all day long; it's Doolittle, Root, A. I., Root, E., and Root, L. C., Heddon, J., T. J. and A. H. Newman, W. Z. Hutchinson, J. P. Israel, Novice, Vandervort, Vandeusen, Pelham, Given, etc., until we, the rest of the community, are afraid to leave home on account of hearing so much about the pesky little things. Now we will wind up as we began. As you saw fit to prescribe the noxious remedy, prescribe the cure. B.

Oak Lawn, Miss., April 26, 1886.

Thank you, friend B., for your graceful compliment. The remedy is to let all these friends put their talk into practical work. If they succeed in putting such nice honey in the stores and groceries that it goes off quickly at a paying price, why, you are all right—just let them go ahead. If, on the contrary, the talk bears fruit in the shape of blasted hopes and disappointment, why, that is the remedy, for no one will follow any thing very long that does not "pan out" so as to pay expenses.

IS SO MUCH CELLAR VENTILATION IN WINTER NECESSARY?

I carried 63 colonies into the cellar on the 5th day of Dec., 1885, and on the 9th day of Feb., 1886, I carried them out for a fly, and found three dead. Four days later I carried them back into the cellar, where they remained till the 13th day of April, when they were again placed on their summer stands. Inside of 2 hours they were carrying in natural pollen. I next lost 2 more by robbing, and sold one. The remaining 62 are in reasonably good shape. They are now very busy on fruit-bloom, and fairly *drop* on the alighting-board. My cellar is an up-ground one, 8 feet by 12 feet in the clear, 6 feet ceiling, and 12-inch walls, filled with dry sawdust, with about 18 inches over the ceiling. An accident occurred which satisfies me that bees do not need as much ventilation as is generally supposed. I have a six-inch tile sub-earth ventilator, and the accident is that the tile became completely stopped for at least 40 days, yet my bees suffered no unusual loss, and came out in good condition.

The two imported queens purchased of you in 1883 are yet doing good service, and are building up their colonies satisfactorily. May I add, I take great pleasure in perusing GLEANINGS? and while I do not indorse *all* of the doctrinal sentiments expressed in the Home Papers, I find enough to make them read and re-read, alone and in the family circle. ELIAS COLE, 68—63.

Ashley, Ohio, April 29, 1886.

Friend Cole, when the weather is very cold it makes but little difference whether your cellar is ventilated or not. Air will force itself through the cracks and crevices as fast as it is needed.

TAKING BEES BY THE DIPPERFUL.

I have never noticed in GLEANINGS or A B C book where any one hives bees as I do, which I think is a very good way where they settle as ours always have; i. e., on the branches of peach-trees, etc. I spread a sheet on the ground and set the hive on it, getting as near under the cluster as convenient. Take a dipper and dip off the lower part of the swarm, and pour them at the entrance of the hive, and they begin to run in as fast as they can. After that I jar the limb two or three times and the remaining bees follow in to the hive. We wintered our bees on summer stands. I think they will generally winter so here (south-west Missouri) if they are strong and have plenty of honey. Our section-box honey has received a great deal of praise, as it is quite a curiosity to a great many in our surrounding country. I do not think there are half a dozen bee-keepers in the county who use the L. hives or any thing similar, and very few keep bees, even in the old-fashioned box hive. I do not see why, when almost every one is fond of honey. We have hands sometimes who can eat ½ lb. at one time; but I have never heard of their trying to have bees at home. MAGGIE I. MIRES.

Houston, Mo., Apr. 13, 1886.

ANOTHER USE FOR THE CLARK SMOKER; HOW TO GET RID OF VERMIN BY THEIR USE.

I think I have something new to communicate to you. Still I have misgivings, as it seems nowadays that there is "nothing new under the sun." However, as I do not intend to get out a patent, even if it does prove to be a valuable acquisition, I shall not feel sorry.

Have you folks in the Buckeye State any gophers infesting your gardens? If you have, you know what they are. In this land flowing with milk and honey, we have them to our hearts' content; in fact, they are one of our worst pests. The only underground animal, or vermin, that is more destructive to the crops is the squirrel.

In neighborhoods where these animals are troublesome, the cultivators of the soil are bothered full sore in devising means to exterminate them. Cats, traps, poisons of various kinds, and other means, have been resorted to, all of which have proven slow and unsatisfactory. One of the latest devices for exterminating squirrels is an iron tube, or pipe, the lower end tapering to a point, while at the other end is a fire-chamber and bellows. With this arrangement, certain kinds of material, which produce a suffocating smoke, is burned, and, by means of the bellows, is driven or forced into the hole of the rodents. These vermin-smokers are, I believe, quite expensive.

Well, now for my patent (?). I have three makes of bee smokers, and the thought occurred to me that I could smoke out gophers and moles with some of them. While in the bee-yard a few days ago I discovered a gopher working; and having one of your cold-blast smokers fired up I went to the rodent's hole, inserted the nozzle till it made a tight fit, so that no smoke could escape, and then I proceeded to puff away. In a short time I found the smoke issuing from cracks and old holes all around me for ten or twelve feet away. I tamped these "leaks," and continued to drive the smoke into the hole so as to fill all the underground passages. Then I stopped the hole and left the rodent to suffocate. Your six-bit smokers take the cake for cheapness and effectiveness in smoking out gophers and moles, and I think they will do for squirrels and rabbits. You might get up a cheap one especially for this purpose. Make them and advertise them in the agricultural press. W. A. PRYAL.

North Temescal, Cal., May 7, 1886.

CAN A LINSEED-OIL BARREL BE CLEANSED SO IT WILL ANSWER FOR HONEY?

Can I cleanse a linseed-oil barrel so as to put in safe condition to hold and not injure extracted honey? W. M. JAMES.

Paris, Tenn., May 12, 1886.

Friend B., I should be a little afraid that the oil would taint the barrel, even if you do your best, although you might make the experiment on one barrel, and test the matter. Wash it thoroughly with soapsuds and ashes and water; then dry it in the sun, and drive up the hoops until it is as dry as a chip. Now coat it with beeswax, according to the plan given in the A B C book; and if you make the wax cover every part of the wood, and adhere to it so it won't scale off, I think there will be no danger of tainting the honey. The great danger is, you will not have the barrel thoroughly dry when the hot wax is put on, then the wax will cleave off, letting the honey come in contact with the oil-soaked wood, and this may give it a taint. In emptying barrels of honey I have seen the wax scale off from the wood in pieces as large as your hand, because some portion of the barrel was not thoroughly dried before the waxing was done. Now, if we have a *tin* can or tank that has been used for linseed oil, there will be no trouble at all; for soap and water, with the addition of a little ashes, would clean it so perfectly that it would be, to all intents and purposes, as good as a new tin. This is one reason why we have of late been so strongly in favor of tin instead of wood for holding and shipping honey.

WHITE-CLOVER JUST COMING INTO BLOOM; WHY DID THE QUEENS DIE?

There were very few bees lost last winter in this vicinity; several wintered every stand. We were not quite so fortunate, but are not by any means discouraged. The apple-bloom is over. Dandelion is in full bloom. They are just beginning on the oak and hickory. White clover is just coming into bloom. The clover bloom has not been more promising for a great while than now. Some have swarmed, and others are getting ready.

What is the cause of so many colonies becoming queenless? Out of our apiary we have had four queens disappear; two that left seven frames of nice brood, with plenty of bees and honey. Mr. J. E. Maury has found four queens missing in unpacking half of his apiary. Other neighborhood apiaries met with similar losses.

Van Wert, O., May 12, 1886. LEVI PERRY & SON.

It is a little difficult, friends, to decide whether your losses of queens are unusual or not, so long as you don't tell how many colonies you have. If you lost 4 queens out of 8, it would be a little remarkable; but if only 4 out of 40 or 50, it would be nothing at all strange or unusual. This is why I always like to have any writer tell the number of his colonies.

HOW HAYHURST AND HIS BEES FARED IN THE RECENT STORM AT KANSAS CITY.

I am thankful that I can report that the awful storm which swept over our city last Tuesday did *us* no material harm; a few of our trees were broken, one being torn all to pieces. In the bee-yard, hives and covers were blown about, and a few were broken by heavy branches from the trees. Few bees were killed, and the enameled sheets protected most of the colonies from the rain. It will give you some idea of the terrible power of the wind, to tell you that leaves from the trees, clover-heads, and even slender blades of blue grass, were torn off and driven with such force against the sides of the hives and honey-house that many of them are there yet, although there was a heavy driving rain against them all day yesterday. Many of the larger leaves are so pounded into the paint that they can not now be removed without scraping. The hives and buildings were freshly painted several weeks ago, and the paint is not yet entirely hard. It required several hours for two of us to clean up the debris in the bee-yard. But, alas! this was nothing compared to the sad scenes of death and destruction in the city. Reports from neighboring apiaries indicate that bees suffered very little.

E. M. HAYHURST.

Kansas City, Mo., May 15, 1886.

HOW TO GET WHAT YOU WANT WHEN YOU VISIT THE "HOME OF THE HONEY-BEES."

I see, by an editorial, that you have trouble with customers making orders personally. I suppose some of your customers besides myself were also vexed; for I thought, after following one of the clerks up and down, I could get the goods half a dozen times myself, and they perhaps thought there was no one in the world as awkward as I am. Next time I took a catalogue and order-sheet and marked the goods I wanted, and handed it to a clerk, who started off with a basket and order-sheet, and in a short time my goods and bill were in charge of the clerk in the counter store, where I settled and loaded up, and was ready to start for home without troubling any one but those with whom my inquisitive nature came in contact. C. WECKESSER.

Marshallville, O., May 24, 1886.

Friend W., I am very glad indeed if you succeeded as well as you say. Since the burning of our warehouse and contents we have been kind o' mixed up and out at sea; but I think we are getting through the season pretty fairly after all.

HOW SHALL WE PREVENT BEES FROM DROWNING IN THE BREAD-PAN FEEDER?

I like these (as I use them) better than any other feeder, but I am somewhat troubled by bees drowning in them. One of your correspondents says he paints his, and sprinkles coarse sand over them when wet. I think it a good idea, and I would paint mine, only I fear the paint might be distasteful or injurious to the bees, especially when feeding pretty warm syrup. Do you think it would?

E. H. McCLYMONDS.

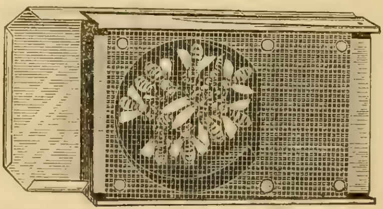
Templeton, Armstrong Co., Pa.

Friend M., instead of paint use melted beeswax, and I am inclined to think no sand will be needed in that case; for a bee that can't stick to beeswax ought to be sent somewhere to serve an apprenticeship.

ANOTHER IMPROVEMENT IN THE PEET QUEEN-CAGE.

AND A NICE PICTURE OF THE SAME.

Is it not pleasant to have nice engravings? There are few things in this world that please me more than to see a really nice picture of something I want to show. Well, just see if you don't think this picture illustrates the point.



IMPROVED PEET QUEEN-CAGE AS WE NOW MAKE IT.

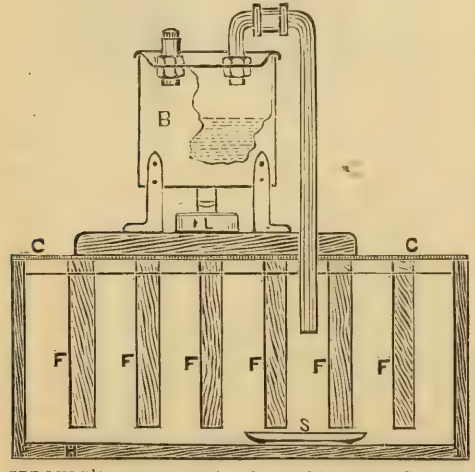
Our engravers have tried once or twice on it, but Ernest complained that they didn't do as well as they might do, and he wrote them quite a letter about it, and both together they managed to get up the above beautiful cage of queen and bees. Why, it looks almost as if you could see the little chaps move around. Even the yellow bands are plainly shown. About the improvement: It is simply in having the wood come up above the edges of the wire cloth, accomplishing two objects; first, the raw edges of the wire cloth are kept from scratching and catching your clothing, etc.; second, when the little board that covers the wire cloth is tacked on the projecting lip of wood, it holds the board up so as to allow ventilation at each side of it. If several cages are to be fastened together, it also spaces them so as to let air in at the ends. Although great numbers of queen-cages have been suggested, all things considered we like the above better than any thing else.

DISINFECTION OF FOUL-BROODY HIVES BY STEAM.

HOW TO MAKE A HOME-MADE APPARATUS FOR THE PURPOSE.

IN the course of a long struggle with foul brood, a great, if not *the* greatest difficulty I had was the disinfection of the hives, feeders, and other appliances which had been in contact with diseased stocks of bees. I tried washing with a solution of salicylic acid (in which, however, I had very little faith, owing to its not being volatile at ordinary temperatures); also with carbolic acid, and fumigation with burning sulphur, but all to no purpose, as the disease reappeared, soon after the bees and brood had been got into a healthy state, when they were placed in a hive which had been tenanted by a diseased colony. After many failures I hit on a process by which an infected hive can, with a trifling expenditure of time and trouble, be effectually cleansed, and rendered fit for use without the least danger of its communicating foul brood to any colony placed in it. As the matter may interest American bee-keepers, I will, with your kind permission, describe my process in GLEANINGS. As I know very little of the hives in use on your side of the Atlantic, a short description of the hives generally used, both in England and Ireland, may be necessary to enable your readers to make allowance for difference in construction when using the process I recommend.

The standard British frame measures 14×8½ inches, and the hive holds from ten to twenty of these frames. The hives are usually made with double walls, the space between being packed with cork dust which Mr. F. Cheshire's experiments have shown to be the best and cheapest non-conductor of heat we have. Instead of the honey-board, we use a covering of carpet, which lies on the frame-top at all times when supers are not on. When I mention the slides by which the entrance can be closed if necessary, I consider my description full enough for the present purpose.



SPROULE'S APPARATUS FOR DISINFECTING FOUL BROOD.

The principle of my process is, passing a current of steam at a low pressure, from a solution of pure carbolic acid and water, through the hive, by which means the carbolic acid in a finely divided state is brought into intimate contact with every part of the hive interior, which is thereby thoroughly cleansed and disinfected. To effect this a small boiler, B, is required, and this I made from an iron paint or ink can as follows: A can to hold 12 lbs. of printing-ink measures about 10×5 inches in diameter. With a cold-chisel it was reduced to five inches in height, and three legs of so-called half-round iron were riveted to its sides so as to raise it three inches. In the cover I cut two ½-inch holes, in each of which I put a wrought-iron nipple, which were screwed in their places with back-nuts, shown in the top of the boiler B. The cover was then red-leaded round its edge so as to make a tight joint, after which it was forced into its place in the can. On one of the nipples an elbow was screwed, then another nipple, then another elbow, and finally a piece of ½-inch G. B. tubing, about 14 inches long. I then got a piece of yellow pine, 12×8×2 inches, and about two inches from one end I made a hole large enough to admit the piece of G. B. tubing. To complete the apparatus, an ordinary tin canister cover (one made of a solid piece of tin without soldering), about three inches in diameter, is required as a lamp, as shown at L. To use it, a wineglassful or two of pure carbolic acid is poured into the boiler B with about double the quantity of hot water, and the open nipple is closed with a suitable cork. The hive H to be operated on is prepared by placing a few empty frames, F, F, F, in position, on which the carpet covering, C C, is laid, a hole about an inch in diameter being made in the middle of the latter. The piece of pine is then laid on the carpet, to form a stand for the boiler, which is placed in such a position that the G. B. tubing passes vertically through both wood and carpet into the hive. The canister cover is filled with methylated spirits of wine, put under the boiler, and lighted. In about five minutes the acid and water will boil, and the steam will pass through the tube into the hive. It may be desirable to place a saucer, as at S, in the hive, to hold the drip from the boiler. At first the steam will condense on the hive-sides and floor-board; but when they become heated, the steam will force its way into every crevice, and at last through the carpet; but it can be confined to the hive by placing a sheet of brown paper between the carpet and frames. About ten minutes' steaming will be sufficient for any hive. To get rid of the smell of the carbolic acid, a current of steam from water only will be necessary. If the boiler is found to leak, a little sawdust put in with the carbolic solution will stop it.

For disinfecting hives, I do not think this simple apparatus can be excelled, and with ordinary care it is most effective. I have used it with over a dozen hives, in each of which a colony had died of foul brood. Those hives have been in use for over two years, without any trace of the disease being visible.

The winter here has been unusually severe and prolonged this year. Although this is the last day of March, we have, at the time I write, a whole gale blowing from the south-east, with showers of sleet at intervals. Taking advantage of a fine day recently, I examined my colonies, and was sorry to find five of them dead. The Carniolans, both full blood and first crosses, were in very good condition, and are, so far as my experience goes, more easily wintered than either blacks or Ligurians.

Dublin, Ireland. ROBERT SPROULE.

OUR OWN APIARY.

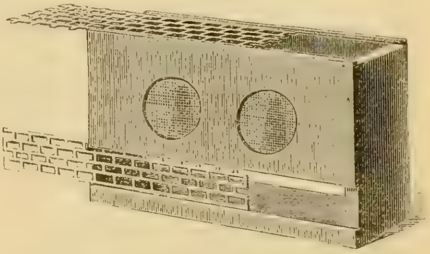
THE ALLEY DRONE-TRAP, AND HOW IT DOES ITS WORK.

IN consequence of so much being said of late in praise of the Alley drone-trap, I determined to give it a test in our own apiary. It may be said that the "Home of the Honey-Bees," so called, is somewhat conservative, and rather intolerant to traps and "fixin's." Our readers, however, may rest assured that a thing possessed of real merit, and about which reports speak favorably, sooner or later shall not lack for a fair trial in our apiary; so with Mr. Alley's invention, although passing under the name of a "trap." I felt morally certain that the invention was a success, but I could not be fully satisfied until I had witnessed its operation, and just how well it did its work. What may be a success to one may not be at all satisfactory to another.

With one of these in hand I proceeded to a chaff hive where had been a drone-laying queen, and, in consequence, at this time there was a great predominance of drones. The construction of the trap is such that it can not easily be attached to a *chaff* hive without the aid of a couple of wire nails. These, driven cornerwise, or toe-nail fashion, as it is called, hold the trap in the desired position. The nails need only just catch the front of the hive, and the trap can easily and quickly be removed or adjusted to any double-walled hive. Or, if more convenient, the sand in front of the entrance can be banked up so as to hold the trap in the proper position. As the former plan happened to be more convenient at the hive where I wished to make the trial, the trap was fastened in that way. This was about 10 A.M., and very soon quite a number of bees hovered in front of their hive, evidently greatly confused at the altered appearance of the entrance. After flying about for a few minutes they no doubt thought that what could not be helped must be endured, and so crawled through when they had thoroughly inspected the perforated metal. A whole day was necessary for the bees to become accustomed to the drone-trap, after which time they passed and repassed as before, but not without some little hindrance. In the height of the honey-flow this would result in the loss of considerable honey, especially if very many of the hives had the traps attached to their entrances. On the other hand, it may be said that the observant apiarist will place the drone-trap in position a day or two *prior* to the advent of a swarm; and as the bees are liable to loaf during this time before coming forth, nothing will be lost.

IS THE TRAP A SUCCESS IN CATCHING DRONES?

Although the hive to which I attached the trap contained a large number of drones, none made an attempt to pass the perforated zinc until about 1 P. M. On coming up at this time I was greatly amused to see them tugging at every available hole in the perforated metal. Their clumsy round heads wiggled and squirmed, but to no purpose. In fact, there were so many trying to make their way through that even the workers could not pass, by reason of the multitude of drones blocking up the holes. To say the least, their efforts were "real funny," as the boy says. After repeated attempts the poor drones resorted to the then remaining place of escape; namely, through the cone in the trap. This, as you are aware, leads into a little chamber where the drones are made prisoners. In about an hour afterward I returned, to find about a quarter of a pound of drones—quite a number of which had bumped around until they had worried themselves to death, and some were dead below, as they had been unable to find the cone. On trying two or three hives in this way I find that the trap gives excellent satisfaction. As has been said, drones can be caught and disposed of accordingly. If one desires to take half a pound or so of choice drones to another apiary, I think I should take the trap away in about an hour after they have begun to collect in the upper chamber. If left longer they will worry themselves to death, as I have found by experience. Perhaps our friends would like to have a cut of the Alley drone-trap reproduced, so here it is.



THE ALLEY DRONE-TRAP.

You observe, through the circular openings, the cones through which the drones pass when they find themselves unable to escape by means of the perforations below.

DRONES BY THE POUND.

I was just wondering whether there were not some enterprising Yankee who would advertise to sell choice drones by the pound. He is to catch them with the Alley trap, and supply them, at whatever cost may be agreed upon, to bee-men having black bees, and who are desirous of Italianizing at a small cost. Of course, the latter are to get rid of their black drones by the aid of the trap before mentioned. It would be somewhat of a trick to ship drones, and I am doubtful whether drones alone could feed upon the ordinary candy, such as is used in shipping-cages. However, we have mailed successfully, in the common Peet cage, about a dozen drones to parties who called for them. If drones were allowed to have access during shipment to unsealed honey, with a few bees, they might arrive in good condition. Possibly we may try the experiment here; and if we succeed we will report later.

OUR PREPARATIONS FOR QUEEN-REARING.

We have to day, May 25, 401 stocks, a part of which are full colonies, and the remainder nuclei. By the time this issue is out we shall probably have many more, as the boys are dividing, with a view of raising as many queens as possible. As Neighbor H.'s and queens of our own raising have given so much better satisfaction than those we buy from a distance, we are going to make an effort to supply, as far as possible, our friends with queens from our own apiaries. I do not mean to reflect upon the friends who have supplied us with queens from the South, for as a rule they have been good. To ship queens a thousand miles and then re-ship them another thousand is certainly not adding to the longevity of the queens or to their prolificness; and, besides, our customers will be better pleased. We intend to increase our colonies up to 500, and we shall make a vigorous attempt to supply, as far as possible, queens from our own apiary. Of course, if the orders pile in upon us too heavily we shall have to call upon those outside of our immediate vicinity.

MEDINA, JUNE 1, 1886.

His leaf also shall not wither; and whatsoever he doeth shall prosper.—Ps. 1:3

HEIGH-HO! One of our Brahma hens has a *nest full* of chickens, after all.

NUMBER OF SUBSCRIBERS AT THE PRESENT DATE.

WELL, there are just 5617—just 95 more than we had a month ago. Many thanks to you all for so much encouragement.

REDUCTION IN PRICE OF DRONE - GUARDS AND DAVIS BRUSHES.

BY referring to our catalogue of the last edition you will see that the Jones drone-guards have dropped from 10 to 5 cts. each, and the Davis brushes from 15 cts. to 10 cts. For rates by the tens and hundreds, see price list.

SUPPLIES BY THE CARLOAD.

GOODS are still going off at a pretty good rate. Our freight and express shipments amount to about a carload and a half of goods daily. With one or two exceptions we have no very old orders waiting. So, friends, we think we are doing pretty well, considering the loss we have sustained in our warehouse. It is beginning to make our faithful old engine look tired.

TERRY'S NEW BOOK.

WE shall be ready to mail the above about the time your order reaches us, probably. Although the book is mainly in regard to the winter care of horses and cattle, it touches on almost every thing connected with successful farming—shelter, comfort, feeding, exercise, kindness, different sorts of feed, with a full treatise on the most economical way of saving manure. A full description of the model barn is given, as shown on p. 396. Price 40 cts.

BEAUTIFUL COMB HONEY FOR ONLY 12C. PER LB.

As the lot of honey mentioned on page 329 of our issue for April 15 does not go off very rapidly, we now offer it, in order to make room for the new crop, for only 12 cts. per lb. It is not only handsome, strictly white comb honey, but it is as delicious as any honey I ever tasted. For weights of the different cases, see reference above. At this low price it must be sold in full cases. Two or more cases, 5 per cent off; 10 or more, 10 per cent off.

GETTING UP EARLY IN THE MORNING.

SOMEHOW I have great respect for the man, woman, or child, who delights to be up during the bright morning hours, and to push ahead in whatever is to be done. Some years ago, about the first of June, one morning before it was quite daylight I saw a couple of boys coming to meet me. One had something in his hand that I found to be a box of strawberries. He was a young bee-keeper, and had driven quite a good many miles to make us a visit, and he had push and energy enough to arrange it so as to get through to Medina in time to see business start up in our big establishment. He had come to buy some supplies, and had brought along some strawberries to trade on supplies. I traded at once on the strawberries; in fact, I always buy strawberries of almost everybody, especially if the berries are fresh, and it is early in the morning. I do not think I told the boys so, but I made up my mind that they would get ahead in this world with bees or strawberries either, and I guess I got it right too. One of the boys was Christian Weckesser, Marshallville, O. You will notice his advertisement of queens and strawberry-plants, and I think you will notice that he is a good straight boy every time — a Christian by name, and a Christian in spirit. Now, I do not know that getting up early in the morning has all to do with his success; but it indicates that he has enterprise and go-ahead, and that is worth a deal in this world. No one can afford to lie abed mornings in the beautiful month of June, as it seems to me. If you do not get sleep enough when you get up at half-past four, go to bed at half-past eight at night, or sooner; but don't lose the beautiful morning hours.

FORGETTING PRESENT BLESSINGS AND PRIVILEGES.

LAST night at sundown the thermometer indicated 47°; by 9 o'clock it indicated only 42°, and there was every prospect of a sharp frost. In talking with my wife I told her that the frost that we should probably get would stop the flow of honey from the locusts, would result in a heavy loss on our strawberries, probably kill or cut down the corn and potatoes, and be death to the cucumbers and our 2000 tomato-plants, many of which have tomatoes on, the size of hens' eggs, besides freezing a lot of other stuff. I thought of building fires, as has so often been recommended, with a view of saving a part of the stuff; but we had so much of it, and all of the fuel was so wet from the recent rains, that it seemed almost out of the question to try it. As I went to sleep I thought of the probable ruin I should see in the morning, and it seemed to me I had never appreciated the comforts that surround us this season. I hadn't even thought to thank God for them as I ought to thank him; but I made up my mind that, if it clouded up, or the temperature changed, so that the things that had become so dear to me (by watching their daily growth) were saved, I should, in the morning, be ready to give thanks in good earnest. Some time in the night my wife made the remark, that the sky was partly clouded over, and that the thermometer was rising; but I was too sleepy to think much more about it than to be thankful. This morning it was warmer, and every thing is all right—not even a leaf withered; and as I look over them to-day I do prize them, and feel happier in the possession of these gifts than I could possibly have done without the frosty air of last evening as a reminder. Then, dear friends, is it not a kindness to us to be reminded occasionally of the blessings we enjoy, by some such hint or warning?

DR. C. C. MILLER'S NEW BOOK, "A YEAR AMONG THE BEES."

THIS is a very pretty little bound volume of 114 pages. It is a plain, familiar talk about bees and bee culture. It starts out in an intensely interesting and taking way, and keeps it up all through the book. One of its particular charms is, that friend Miller does not pretend to know all there is to be known in the matter. He does not get up on to any high rostrum at all, but talks about the business just as one farmer would naturally talk to another about seeds, manures, implements, etc. He tells of the way in which he has worked, and of the short cuts he has made. He tells of his blunders, and frankly says a good many times that he does not know just the best way. As an illustration, after having tried almost all kinds of feeders, and after having had them in the way after he got through with them, perhaps forgotten and left in the hives when they ought not to be, he decides now in favor of having no feeders at all. But where a colony is to be fed, he does it by filling empty combs with syrup, in a manner similar to that given by our old friend Quinby, years ago. His wife and his boy assist him in the work, not only with their hands, but with their brains; and I tell you, my friends, it is a big element toward success to have a good smart woman to help you in the bee-business. Very likely it is in any kind of business; but a great part of bee culture is emphatically woman's work. Friend Miller has a particular way of placing his hives by twos; and if there is any thing about the book that is lacking, it is that he did not give us a nice picture of an apiary arranged the way he would have it; and, by the way, more pictures of other things he describes and speaks of.

Friend Miller is not only a genius, but he is a man who has proved his ability to manage bees, by making money at the business; that is, he made money during favorable seasons; during unfavorable seasons, he frankly owns up, he has not. I think it will pay every one who has a dozen colonies of bees or more to have "A Year Among the Bees." Price 70 cts.; 10 or more copies, 50 cts. each. If wanted by mail, add 5 cts. each for postage.

TOBACCO COLUMN.

I HAVE been using tobacco for upward of ten years, but have stopped since Jan. 1. If you will send me a smoker, I hereby agree to send you pay for the same if I again commence; but I will not commence again, as I fairly loathe it now. WM. F. BEACH.

Philadelphia, Pa., March 23, 1886.

I will take you up at your offer, to send me a smoker. I will give up smoking tobacco.

SAMUEL MUMMA.

Highspire, Dauphin Co., Pa., April 14, 1886.

I send you these few lines to let you know that I have resolved to quit the use of tobacco, after the use of the weed for 7 years; and I now promise myself that I will not use it again. If you think I am entitled to a smoker, please send it; and if I ever break my pledge, I will pay you full value.

Cass City, Mich. J. W. WRIGHT.

The smoker and "Truth" are duly at hand, for which please accept my thanks. Will do as I agree to do. My tobacco has gone. JOHN ARNER.

Rimersburgh, Pa., March 29, 1886.

I have left off using tobacco. I wish you would send me one of your bee-smokers. I hereby promise, if I ever use tobacco again I will send you the money for the smoker. F. H. YORK.

North Norway, Maine, March 29, 1886.

Having formed the acquaintance of L. B. Polk, who is engaged in the honey-business, I have, through him, gone into it. Having chewed and smoked from boyhood, I have quit. Please send smoker; and if I ever begin I will pay you for it.

R. SIMKINS.

Anderson, Ross Co., O., Apr. 19, 1886.

I commenced chewing about two years ago. A few days ago I thought I would would quit using tobacco. I heard that if any one would quit the use of it you would send a smoker as a present. If I ever commence using it again I will pay you full price for it. J. C. STEPHESON.

Burlington, Burlington Co., N. J., Mar. 8, 1886.

INFLUENCE OF A 14-YEAR-OLD BOY OVER HIS FATHER.

I am 14 years old, and commenced to keep bees last summer. My father has chewed tobacco for 20 years, but he quit last May, and told me I might try for a smoker, and he promises to pay you the price of one if he ever touches it again.

Ypsilanti, Mich., April 13, 1886. A. F. SMITH.

A STITCH IN TIME.

I saw, while I took GLEANINGS, that you had much to say about that nasty weed tobacco, and also that you gave a smoker to any one who would quit using it. Well, put my name down on that list for two smokers—one for myself, the other for my neighbor, who has also quit its use. I have just gone over into my twenties, so I quit while young, and a "stitch in time" will count nine. You can send both smokers to me, and I will stand good for both. Should I begin using it again, I will pay you for both smokers. Both my parents are slaves to it, and I can see its evil effects. Bees have all wintered well in this locality this year, and carried in pollen March 18th for the first time this year.

MICHAEL BUSCHER, JR.

Cicero, Hamilton Co., Ind., Apr. 14, 1886.

QUIT FOR LIFE.

I am a rather poor hand to beg; but I learn from GLEANINGS that you offer a smoker to any one who has been in the habit of using tobacco, and is willing to quit. I see, also, that those who get a smoker, and then take up the habit again, must pay for the smoker. I have quit for life; and if I am entitled to a smoker, please send it by mail and I will pledge myself to pay you for one dozen smokers if I ever use tobacco again. I smoked for 9 years, and have seen the folly of the filthy practice, and have been the means of turning others from it. I have read of several in GLEANINGS who say they have not got to pay for their smoker yet; but I read to-day of two who had sent in the price of smoker to you, stating they had forfeited their contract, and had gone to smoking again. This is all wrong.

A. B. GEORGE.

Newberg, Yamhill Co., Oregon, Mar. 26, 1886.

ITALIAN & CARNIOLAN QUEENS.

Bred in separate apiaries, away from other bees. Warranted Italian or untested Carniolan queens, in May, $1.25; 6, $6.75; June, $1.10; 6, $5.90; July, $1; 6, $5. State which you prefer, Italians bred from my *Bellinzona strain*, or *Golden Italians*. I am prepared to please all.

KIND WORDS FROM OUR CUSTOMERS.

I received your A B C book and am very much pleased with it. The book is worth $10.00 to any beginner. C. S. JOHNSTON.
Emlenton, Pa.

C. C. MILLER'S OPINION OF OUR NEW INCUBATOR THERMOMETERS.—SEE P. 297, APR. 15 ISSUE.

Many thanks for the thermometer, which has come in perfect order. You don't know the comfort I feel in owning a thermometer which tells temperature so plainly, and in whose word I can have such confidence. I feel very grateful to you for teaching me the use of wire nails, which are now introduced for the first in the Marengo stores.
Marengo, Ill., May 22, 1886. C. C. MILLER.

A YEAR AMONG THE BEES.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

OFF-COLOR ALBINOS!

Friends, I shall have a good many Albino queens this summer through, which, when tested, will not come up to the standard for which I shall breed in stocking up my 60 colonies. *These* tested queens, which will be good, but off colors, I will sell for 50c. each. Those wanting, send orders and I will fill as I have them to dispose of. **ABBOTT L. SWINSON,**
Goldsboro, Wayne Co., N. C.

I have made arrangements to supply about 25 black queens this month. Those wanting them can have them for 25c each, or 5 for $1.00. Order at once. **A. B. JOHNSON,** Clarkton, Bladen Co., N. C.

Having 30 hybrid queens I will send them to the friends for 50 cts. apiece, by return mail, this month. These queens were all raised last year, and from best imported and select tested queens. Postage-stamps accepted. Address **JNO. A. THORNTON,**
Lima, Ills.

Black and hybrid queens at 25 cts. and 40 cts. apiece. **GEO. D. RAUDENBUSH,** Reading, Pa.

Choice hybrid queens for the next three months, 25c. now. Safe arrival guaranteed. **G. S. FOX,**
Mitchellville, Iowa.

Friends, I have 30 black queens that I will take 25 cts. each for, or 5 for $1.00. Ready to ship now.
RICHARD MCBRIDE, Ammon, Bladen Co., N. C.

I have some mismated Italian queens that I will sell at 35 cts. each; pay for them when received. Can get black queens at 25 cts. each.
W. A. SANDERS, Oak Bower, Hart Co., Ga.

I have ½ dozen or more hybrid queens of last year's raising for sale, at 35 cts. each, ready to mail on receipt of order. **O. H. TOWNSEND,**
Alamo, Kal. Co., Mich.

Hybrid queens from pure mother, 50c; blacks, 25c.
W. T. LYONS, Decherd, Tenn.

WANTED.—A partner to take half-interest in an Apiary, with a little capital. Address

HONEY COLUMN.

CITY MARKETS.

ST. LOUIS.—*Honey.*—We quote honey very dull. Nearly all offerings are of old stock, which is hard to place, even at low prices, as follows:

Old strained, in bbls. and kegs,	3@4c
" extracted " " " "	4½@5½c
" " " cans,	5@8c
" comb, broken,	5@7c
Choice cap,	10@12c

There is a fair demand for choice and fancy new white clover, in 1-lb. caps, at 13@15 cts. *Beeswax* has good demand. Selected yellow, 22½@23. Prime, 22, dark, 18@20.

With the present low prices on all kinds of products, we can not look for high prices for the product of the busy bee. W. T. ANDERSON & CO.,
June 12, 1886. 104 N. 2d St., St. Louis, Mo.

MILWAUKEE.—*Honey.*—Honey is in only moderate demand for comb in sections, and the supply limited. Extracted, ready sale on arrival, at prices according to quality and quantity. Quote choice 1-lb. sections, 16@17c; choice 2-lb. sections, 15@16. Extracted, in bbls. or kegs, 6@7½. *Beeswax* wanted, 24@25c. A. V. BISHOP,
June 11, 1886. 142 W. Water St., Milwaukee, Wis.

CHICAGO.—*Honey.*—Very little comb honey here at present, and none of the best grades of one-pound combs; we expect to have some of the new crops soon. Extracted is without change of any kind. *Beeswax* scarce at 25c. R. A. BURNETT,
June 10, 1886. 161 S. Water St., Chicago, Ill.

DETROIT.—*Honey.*—No honey in market to quote, and but little wanted. Fruit seems to take its place at this time of the year. *Beeswax*, firm at 25c.
June 11, 1886. M. H. HUNT,
Bell Branch, Mich.

CLEVELAND.—*Honey.*—The demand for honey has fallen off very rapidly since our last report, owing, undoubtedly, to the near approach of the new crop. Prices are nominally unchanged. Choice white 1-lb., 14 c; 2-lbs., 12c. *Beeswax*, 25.
June 10, 1886. A. C. KENDEL,
115 Ontario St., Cleveland, Ohio.

12d **E. A. GASTMAN, Decatur, Ill.**

SPECIAL OFFER.

After this date I will furnish untested queens for 75 cts. each, $4.00 per ½ doz., or $7.50 per doz. Tested, $1.50. Warranted queens at $1.00; 2-frame nuclei, with untested queen, at $2.00. Ref., A. I. Root.
Address A. B. JOHNSON,
12d Clarkton, Bladen Co., N. C.

Good Luck.

Trout, bass, pike, pickerel, or any fish that will take an artificial bait, can be caught by using my new trolling spoon, sent on receipt of 25 cents; also 600 feet of linen trolling line, for one dollar; 216 feet linen pole line for 30 cents. Trout-hooks to gut, ten cents a doz.; large hooks for bass, pike, and pickerel, doubled gut, 20 cts. per dozen.
C. H. WILCOX,
12d Earlville, Madison Co., N. Y.

GLEANINGS
IN
BEE CULTURE.
DEVOTED·TO·BEES·HONEY·&·HOME·INTERESTS.
F.A. Whiting

Vol. XIV. JUNE 15, 1886. No. 12.

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00; 10 or more, 75 cts. each. Single Number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent TO ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

GETTING BEES OUT OF SECTIONS.

ADVANTAGE OF HAVING ITALIANS INSTEAD OF BLACKS OR HYBRIDS.

ON page 393, Geo. A. Wright asks how to get bees out of cases. Now, friend Wright, if you'll promise to say nothing about it I will say to you that I have not yet learned to do it to my satisfaction. But as it is a seasonable subject I will tell what I do know, as some of less experience may be benefited thereby.

There are usually two classes of bees in the sections when opened. There are young bees that are timid, and anxious to get out of the way; and, if I am not mistaken, especially anxious to get away from the light. There are old bees that are not timid; and, unless frightened, prompt to make attack; and, when frightened, eager to fill their honey-sacks. We must take into account these two classes of bees, and act accordingly. If we quickly take off a super, or case of honey, and remove it from the hive without giving the youngest bees time to crawl down into the hive, these latter, not knowing the way back to their homes, are liable to be lost if they leave the sections, and are, moreover, loth to come out to the light, especially as they know of no other place to go. I have seen some of them clustered together 24 hours or more, apparently condoling with one another as to their loss of home and friends. It is best then to give these bees time to crawl down into the hive or super below. I am not sure whether these youngest bees wait to load up with honey before leaving the sections; but the old bees, on being alarmed, start at once for the honey-cells, and no amount of smoke short of actual suffocation will induce one of them to leave the honey-cell into which it has plunged, until its load is complete. So far as the old bees are concerned, I suppose they could just as well fill up after the super is removed; but we want to give the young bees time to get out. If you watch a bee filling itself with honey you will find that it takes the best part of two minutes. Perhaps it is best to allow five minutes after opening the super before removing it. This will be a very slow process if each one is taken separately, so I usually open four or five in succession before removing any. This gives the bees plenty of time to get out of the way, without wasting my time waiting. Each super, on being opened, receives five or ten good whiffs of smoke, and I then pass on to the next, leaving the first entirely open, if there is no danger from robbers. If robbers are likely to trouble, a rubber cloth, or piece of cotton cloth is thrown over. By the time the fourth or fifth is open, the first is ready to remove, after receiving another dose of smoke, or, what is perhaps better, several vigorous puffs of the breath. The super is then carried into a room of the shop, which is darkened all but one window, or hole in the wall, arranged, in the way so often described, so that bees will go out but not come in. If, however, honey is coming in freely it is usually safe to set the super beside the hive and let the bees leave the super entirely before taking in. I have sometimes let them stand so till my forenoon's work was done, and then gathered all up. Close watch must be kept to see that the bees do not begin carrying off the honey. If wide frames with closed top-bars are used, the frames must be separated on first opening, taking out one frame if necessary. It may be objected, that the bees thus left to fill themselves will take just so much honey out of the sections. That is just what I like to have them do, for there are always unsealed cells around the outer margin of a section, and the more honey taken from these the better. The bees will not take the trouble to tear open the sealed cells as long as they can find these unsealed ones. I know I have seen sections so badly riddled with holes which the bees had dug in the sealing as to be unsalable; but I have seen very little of it lately. It may be that it is caused by the bees being panic stricken by too heavy a dose of smoke, making them frantically dig into the first cells they come to; but I think it more likely it is the kind of bees. The blacks are, perhaps, the worst. The obvious remedy is to change the strain of bees. I have doubts whether bees addicted to this habit are desirable in other respects.

FIGWORT.

Once when Prof. Cook honored us with his presence at the Northwestern Convention at Chicago, I spoke discouragingly of my attempts at artificial pasturage. In his mildly deprecating way, Prof. Cook begged me not to throw cold water upon the project; and although my efforts have mostly ended in failure, I am not without hope that some progress may be made. In my last article in GLEANINGS, I recounted my virtual failure with an acre of figwort. Well, I have just been down to look over that ground. Neither plow nor hoe has been struck in it since the summer I planted the figwort. I am very glad now to be able to give an encouraging word. Where the figwort stood there was no sign of a plant to be seen this time last year; but now a good many plants are to be found, which, although neither large nor strong looking, give hope that a self-supporting stand may be secured. But for the space of three rods east of the figwort patch, the ground is well covered with strong vigorous figworts, which gladden my eyes. These came, undoubtedly, from seed blown from the old plants, and I have some hope of living to see a five or ten acre field well covered with a mixture of figwort and melilot. I bought and gave away this spring several hundred basswoods.

C. C. MILLER, 340—222.

Marengo, Ill., June, 1886.

Friend M., your suggestion, that the race of bees has much to do with it, is a valuable one. I remember of having a colony of hybrids that I wished to requeen because they were so extremely ugly. Well, they had what I considered a very fair amount of sealed stores for winter; but after swarming them and looking the hive over two or three times to find their hybrid queen, they had uncapped and gorged themselves with nearly all sealed honey from the hive. Instead of putting the honey back in the cells and sealing it up they built new combs in several parts of the hive, and in this way used up and wasted a good many pounds. The kind of hybrids that run all over the combs, then collect on the lower corner, and drop off on to the ground, are the kind that dig open the honey-cells whenever the hive is opened. I do not believe it pays to have such bees in the apiary.—In regard to figwort, I have just found one single plant in our plantation, that was covered with blossoms filled with honey the first of June.

A VISIT TO BEETON.

Friend W. F. Clarke Tells us what is Going on There.

NO "HIBERNATION" AT BRO. JONES'S.

IT is four years or more since I was last in Beeton, until the other day, when I fulfilled a long-cherished intention of again visiting that now renowned spot. How rapidly time flies! During the interval I have emigrated to Winnipeg and returned, bringing home with me the rheumatism, which is the plague of my life. Our bee-circles have been enlivened with the pollen, reversible-hive, and hibernation theories. A new hive and a new system of bee-manipulation have appeared on the scene. A fit of authorship has seized on "severals" of us; e. g., Rev. W. Ballantine, J. Heddon, Mr. Alley, Dr. C. C. Miller, and, finally, on myself. This was the immediate cause of my trip to Beeton. I went there to arrange for getting out my "leedle" book; but as I have disposed of the copyright to Jones, Macpherson & Co., I can leave the *Canadian Bee Journal* to introduce my literary venture, "A BIRD'S-EYE VIEW OF BEE-KEEPING," to the apicultural public.

Beeton has not been at a standstill during these four years. The village is improving much. More tasty buildings, shade and ornamental tree planting, and the adoption, on the part of the county, by local option, of prohibition, are conspicuous evidences of progress. Our friend Jones has not been idle. A better house and larger grounds give scope for his own æsthetic predilections outside, and those of his wife, who is quite an artist, inside. A big job of evergreen planting was on hand at the time of my visit. I never saw so fine a lot of spruces as those Mr. Jones was transplanting, by the hundred, from their native woods, about six miles off. Now for the first time he is fixing up the home apiary; and when it is finished it will be the envy and delight of all apicultural visitors. The shelter will be complete and the protection perfect. It will be the paradise of outdoor wintering and—*hibernation!*

Even more enlargement and improvement are visible around the factory and offices. The machinery for manufacturing hives and various bee-keeping appliances made of wood seems as near perfection as it can be. Driving force is furnished by an 80-horse-power steam-engine, which is itself a very superior piece of workmanship. I did not know saws could do such fine and smooth work until I saw them at it the other day. No need of any planing after the material leaves the little buzzers that run with almost lightning speed. The accuracy with which the various operations are performed, and the close fitting of the parts (dovetailed brood-frames, even, requiring neither glue nor nails) filled me with admiration at the pitch of achievement which has been reached by the ingenuity of man. All hands were busy putting up 500 of the new-style Heddon hive, which is going to get a fair and thorough trial the present summer by Canadian bee-keepers. Fifty had already been shipped to Mr. J. B. Hall, and Mr. Jones intends to use that number, at least, himself. He is making them of thinner material than Mr. Heddon does, and they are certainly a marvel of lightness combined with strength. While retaining the principle and general style of construction, some modifications are being introduced, which I think the inventor will own to be improvements when they are subjected to his inspection. It would take too long for me to go into further detail as to the manufacturing department of this great establishment; suffice it to say, it appears to be very completey equipped, as it may well be, since here are from $25,000 to $30,000 invested in buildings, plant, lumber, and other material. The tin-shop, offices, wax-room, store, and show-rooms are somewhat scattered around at present. All these are to be combined in one large brick building, soon to be erected, in connection with the factory.

Meantime the practical part of bee-keeping is receiving full attention. Besides the home apiary I visited two of the out-lying yards. All are in excellent condition, and awaiting the arrival of the busy season, "ready, aye, ready," to gather in tons of stores as soon as they are to be had. Mr. Jones is perfecting a new system of queen-rearing, of which I am not at liberty to speak in detail. It is going to revolutionize that branch of bee-keeping, and make it "as easy as rolling off a log" for bee-keepers to have on hand at all times a full supply of laying queens. The cost of production will be so cheapened, that we shall smile at the old idea of dollar queens! Thus, all things tend to lower the cost of honey. 'Tis well; for we have not only to drive glucose and other vile adulterations out of the market, but enthrone honey here as the queen of sweetness, both in quality and price. Mr. Jones is also working hard at the devolopment of his plan for obtaining *Apis Canadensis*—the coming bee—by a judicious combination of the best qualities of several races. Operations on the Georgian-Bay Islands will probably be suspended the present summer, as Mr. Jones expects to go to England in August, he being one of the commissioners in charge of the Canadian exhibit of honey at the great Colonial and Indian Exhibition, which is now in full blast at Kensington. So soon as this season's crop of honey is gathered, the best of it, in the most attractive packages, is to be sent to this great show, in charge of five commissioners, by whose patriotic endeavors we expect to have a market opened for our honey product in Great Britain, which will give us a constant outlet for our surplus at good figures.

Mr. Jones's many friends will be sorry to learn that he suffers occasionally and acutely from an ophthalmic affection contracted during his tour in Oriental lands. He had a touch of it while I was at his place, and it evidently causes much pain and annoyance. Total rest of the eyes appears to be the only source of relief, and this is not easy for one who has literally so many things to "see to." He has, however, a most valuable and efficient coadjutor in his wife's nephew, Mr. F. H. Macpherson, who is now his partner and general manager. Mr. Macpherson is an excellent practical printer, as is manifest from the style and appearance of things in the office under his control. Besides the *Canadian Bee Journal*, the *Beeton World*, a local paper with a considerable circulation, is printed and published here. There is also a large and increasing job business. A press of greater speed and capacity is about to be set up, in order to overtake the accumulating amount of work.

Mr. Macpherson is on the eve of following Ernest's example in the way of swarming off and installing a domestic queen. He is fortunate in having "the leafy month of June" for the wedding-trip. I bespeak for him and his bride the hearty congratulations and good wishes of all who read these lines, and I feel sure that all will join me in wishing the happy couple joy of their union, and many long years of conjugal bliss. W. F. CLARKE.

Guelph, Ontario, Canada, June 1, 1886.

Why, friend C., your description almost makes us feel as if we were on the grounds, and catching the infection of so much business, and of a business, too, that is so widespread in its nature that it catches on to almost every land and clime where honey-bees find a home.—We regard it a privilege to be able to say God-speed to friend Macpherson and his bride. I had a short acquaintance with him, and an opportunity for a little talk, during my visit in Toronto, and I was pleased to note that he is business, every inch of him, and a man who is well up with the times, and capable of grasping the great important points of this busy world as it is spread out before us.—I am very sorry for friend Jones's affliction, and it must be an affliction in good earnest if it is something that he does not turn off with a laugh, as he does almost every thing else. How I should like to see him in his busy field of work! I am afraid, however, that the building of our own factory, consequent upon the fire, will again postpone the visit I had proposed making this coming fall.

PROSPECTS FOR THE SEASON EXCELLENT.

GOOD POINTS IN FAVOR OF SPANISH-NEEDLE HONEY.

YOU tell us not to write any thing on the subject of wintering just now, and we must obey, I suppose. I will say nothing about it, except that I came through with 57 out of 60 stands, 50 of them good ones, and that I experimented some with absorbents and no absorbents, which did not quite satisfy me. I intend to make a more thorough test of that next winter. The three stands that I lost became queenless, and I simply united them with others.

This spring, especially April, has been the most favorable vernal season I have had yet. This is my fifth season in apiculture. Gooseberries blossomed almost a week sooner than usual; apples ten days sooner, white clover was about two weeks sooner, and I was quite surprised to have a swarm May 18th, some twenty days earlier than I have ever had one before. My prospects are all excellent, although, while the meadows are white with clover, not much honey seems to be coming in. The weather is favorable too. I do not know how many swarms I might have had, had I not forestalled them and swarmed them myself.

SPANISH-NEEDLE HONEY.

I was much interested in Mr. Andrews' article concerning Spanish-needle honey, on page 357. I quite agree with him concerning the points of this excellent honey. It is the richest honey stored in this region. What little I get of it I like to put aside for my own use. Its dark color is no detriment to its sale where it is known, and a great many folks around here know its good qualities too, and prefer it to any other. It is much less apt to sour than white-clover honey; but when extracted, if it does not granulate it tends to acquire a strong, unpleasant flavor. In the comb it retains its fresh flavor better than any other gathered around here. As for wintering bees on it, in spite of all that the books and journals teach about the dangerous qualities of late stores, I can not see but that it proves as wholesome as any gathered early in the season. I have wintered bees well on stores gathered almost wholly during the last half of September. My great misfortune is, that although there is a great deal of Spanish-needle blossom, because of cool or dry weather but little surplus is obtained from it. GEO. F. ROBBINS, 69—57.

Mechanicsburg, Ill., May 25, 1886.

Friend R., what you say about Spanish-needle honey reminds me of an incident of nearly two years ago. I purchased quite a lot of this honey from friend Andrews. He did not tell us what the source was, and I pronounced it a splendid article of goldenrod honey. The color was dark gold, and the flavor excellent, and the body so dense as to give point to my little story. A man ordered a 100-pound can of goldenrod honey. We sent him this, supposing at the time, of course, that it was genuine goldenrod of superior quality. He did not respond according to promise; and when we succeeded in making him answer, he said the honey was poor, and that he could not sell it. We at once told him to return it. Finally it came back. But imagine our astonishment, after unsoldering the tin that held the cork in, to find nothing but water, slightly sweetened, in the can. As the bottom of the can seemed quite heavy, however, we poured the water off and found 42 lbs. of this thick heavy honey uninjured. Our friend had supposed the water would so mix with the honey during the transit that it would sustain his claim that it was a poor article; but as it was in the winter, he missed his calculation. The heavy body of the honey prevented it from mixing. I demanded pay for the honey he had sold out of the can. He denied the charge, and we had to employ a lawyer to make him pay for his attempted swindle. He finally did pay, but it took all of the money he handed over, to pay the lawyer. Now, lest this man should try to serve some of the rest of the bee-friends the same trick, we give his name and address here: E. W. Bramen, Geneva, Ashtabula Co., O. When I met friend Andrews at the bee-keepers' Congress in New Orleans, he told me he was satisfied the honey was from Spanish needle. I agree with you, that it should be ranked as one of the finest, if not the *very* finest, source of dark-colored honey.

THE BEES AND THE NEIGHBORS.

FRIEND DAYTON CONSIDERS PRETTY FAIRLY THE SITUATION FROM DIFFERENT POINTS OF VIEW.

THE description of the "mill" I passed through some time ago, and a few things I learned while there, may not seem superfluous. I agree with many who have written before me, that some people are surprisingly nervous and jealous when they have a bee-keeping neighbor, and the more so if he is successful. A sure way to please them is to dig stumps and pull weeds for a livelihood. It seems to be a bee-keeper's destiny to get between neighbors who are bound to wedge him and his so as to come within "hands' reach" of each other. This state of affairs exists more or less everywhere; but they do not report so much as bee-keepers do. But there is a possibility of two sides to this question. If the bees are situated on a level within 200 feet of the neighbor, and there is nothing intervening, they may trouble him considerably. If they are within 30 feet, and a hedge is near the hives, and a dense row of trees near the hive, the neighbor probably would never be troubled.

To make it dangerous because of stings, outside of the apiary, we may place trees and tall obstructions among the hives. To throw the danger inside the apiary, set the trees on the outside. Wherever we furnish the bees a playground, there is also a place they are going to defend. There always is a place in or near every apiary, clear of obstructions, that the bees are going to occupy for the purpose of flying, and we must surrender it to them or suffer the consequences. By contrivance, and sometimes without contrivance, we may throw their playground in different directions, and it may be into a neighbor's garden.

My apiary is in the village, with four rows of trees as described, and they can find no fault with the bees, and have despaired in the undertaking. One season before I set out the trees, out of 92 swarms 4 were drifted by the wind on to my neighbor's premises. He tried to act wild at the damage they were doing in clustering on a fence-post 5 feet from the line, though in the evening his hogs were digging my potatoes. He would not allow their removal with the swarming-box, though it could be done from my side of the fence. Unknown to him, I rubbed the cluster so harshly with the box that the bees drove him into the house, and I had matters in my own hands. When I found out this state of affairs, I clipped the queen's wings; but a second swarm, with a virgin queen, got away and went over. I asked a justice to get them, and in a berating manner he told me to tender the neighbor a quarter in case of trespass, and take them without ceremony. As I considered a "lean compromise better than a fat lawsuit," the neighbor hived and fed them for winter, but they died because of a lack of upward ventilation.

For two years I rented a part of my house to families to show the neighbors how dangerous the bees were, and they hitched teams within 15 ft. of the rows of hives, hundreds of times, and, fortunately, there was no one stung during the time. The secret lay in a thick row of bushes intervening.

Since the trees I planted began to cast sizable shadows, the neighbor informs me that if I will move the trees I am welcome to come after swarms. The trees may be trimmed; but if they are removed entirely, I fear it will soon be, "Move your bees or we'll move them for you." "Who sows brambles should not go barefoot."

There are many other neighbors who appear to be glad to take swarms from their own trees and bring them to me, and are frequently boasting how they can go in and about the apiary without molestation by bees. When the hives are set close to a fence, and there are trees on the inside, the bees will be caused to go over the fence in their flights. If the hives are located under our trees, then the bees become accustomed so as to follow and search under trees to sting.

Again, when we establish an apiary among neighbors, and provide no trees or high fences to raise the bees high in the air in their flight to and fro, the continual passing becomes a real annoyance. Persons who are not used to the handling of bees would regard their chances of harm about as a bee-keeper would so many flashes of lightning; and though he may never get stung, he will carry fear with him as though it were a heavy weight; and, being a very peaceable neighbor, he will say nothing but wish himself a thousand miles from an apiary. Hence, in locating an apiary the hives should be placed in a clear open space in the center of a dense grove of trees, that they can not be seen or heard. Then when the "chronic growler" finds them in mischief he will not be so hasty to declare evacuation, but he will be awakened to the fact that there are bees in the neighborhood, and will set out to line them home and will figure *damages*.

We should manage to keep our bees from stinging any one outside of our inclosures, and then they can not very well become a nuisance. If there were a dozen cider-presses, groceries, or other places of business, and all were obliged to be exposed to the bees, and there were enough bees to monopolize matters, then the bees might become a nuisance, and their removal might be necessary. There is an exceptional raid made upon somebody's meal, rain water, sap, cider, or kitchen; it can not amount to more than an ordinary damage, and ought to meet an easy and ready settlement. When a neighbor's poultry or stock plunder the property of another they don't cry, "Git for the timber" or back fields, because they know the laws respect poultry and stock, and our country is proud of them; and it is going to be the same with bees as soon as people can be taught their usefulness, and that they do not "work for nothing." So long as we can succeed in selecting intelligent officers, the law is not going to "throw down and drag out" respectable industries for trivial offenses.

There are those whom the sight of a few bee hives affect as an "eyesore," though they reside many miles away; who may talk, as it is cheap, and their stupidity allows their ignorance to lead them to law without a case. Having a neighbor of this "stamp," it is not best to "pull up stakes" to settle down by another; but while he "blows" we should endeavor to clear the way by our works and acts, that others may see that there are some fools yet living.

It has been advised to entice tranquillity by giving sections of honey, etc.; and I am not certain but the effect, when given to a good neighbor, is the most advantageous—making them so loud in our praise that the enemy is glad to retire for his own safety.

The inquiry is often made, whether there is any law regarding bees, to which I might say that there is none, other than what is in harmony with the reason of the case, and which is often greatly varied by the designs and reasoning power of the reasoner. When bees begin to play their part in the courts, then will the law regarding bees develop. Out in California, Mr. Bohn was brought to law for damages done by his bees to grapes. Eye-witnesses testified and swore that the tongue of a bee was so constructed as to pierce the skin of a round grape, and Mr. Bohn was beaten. If the same were said of a cow's tongue piercing a sound squash, it could not be more absurd. That is the kind of material hurled at the bees, when their side is not well represented; and of just such bricks as that will the wall protecting bees be constructed, unless bee-keepers wake up and exert themselves in their interests. At present I know of nothing better through which to act, than the "Bee-Keepers' Union." In fact, I do not know but that that organization is doing as well as could be desired, except that its short roll of members should be lengthened. With ample backing, cases may be won, leaving "marks" that shall ever be pleasing to ourselves and the rising generation. For awhile, bee-keepers have the opportunity to effect laws in their favor; but a superfluity of drones may alter results surprisingly. C. W. DAYTON.

Bradford, Iowa.

Friend D., I quite agree with you in regard to the advantages of a barricade in the shape of bushes, trees, or a tall tight board fence. I have been advising the same thing for some little time back; but you seem to have gone over the ground more thoroughly in your past experience than I have done. I do not believe that, as a rule, it is best to purchase the good will of our neighbors by gifts of honey. If they have sustained damage, for instance where clothes are so badly soiled on washing-day that they have to be rinsed over, I would send over honey enough to pay them well for the time occupied in making good the damage; or I would in any case be liberal with honey or money either, where it would help to make permanent pleasant relations between ourselves and our neighbors.

It has been suggested that the whole matter comes in under about the same aspect as the keeping of poultry. Chickens frequently do a vast deal of mischief, and make untold annoyance. How can it be got along with? I suppose you know there are various ways. A Christian man (that is, one who *is* a Christian—mind, I do not mean one who professes) will either shut up his chickens or move them away when he is satisfied they are annoying his neighbors. Our nearest neighbor is a good old lady who lives right across the street, all alone by herself. Well, her chickens showed a fondness for promenading on our sawed-stone flagging across the lawn. We did not mind so much the presence of the chickens as the presence of something which didn't go by scaring so readily as they did. In fact, it took a scrub-broom and bucket of water to restore the appearance of things. Well. when our neighbor found it out (we didn't tell her of it — she was bright enough and kind enough to notice the trouble her chickens were making us) she said at once she would sell the chickens, and asked me if I would buy them. She did not put it in just so many words, but it amounted to this: If chickens make my neighbor to offend, I will keep no chickens while the world stands. I have remembered this kindness many times. She is alone in the world, and no doubt her chickens were a good deal of company and comfort to her; but off went their heads just as soon as she found they troubled us. May God bless good old Aunt Margaret! I wish there were more Christians like her, even if she does belong to the Catholic Church.

SOMETHING FURTHER IN REGARD TO THE STRANGE FACT GIVEN ON PAGE 422.

A SUGGESTION IN REGARD TO GETTING SWARMS TO LOCATE IN A PARTICULAR LOCALITY.

I RECEIVED your letter, but did not understand it exactly. In consequence of sickness and other troubles I have not been able to write sooner to ask if you ever published an answer to my request. In the meantime, more bees have arrived to reinforce those already here, and I am in sore distress. I don't know any one who will take out the bees now, and, unless I know what to do to prevent the return of the bees, the expense is too great for me to undertake it.

Be so kind, if you ever publish any thing that will help me at all, as to send me the copy of GLEANINGS containing it? I shall be glad to know the scientific fact I furnished you. C. T. FENWICK.

West River, Md., June 1, 1886.

It seems from the above that still more bees have arrived to reinforce those having already taken up their abode in our friend's house. Now, is there not some bee-keeper near West River who can look into this matter and tell us more about it? It is rather far away to send one of the editorial staff of GLEANINGS to look up the matter, but I am afraid we shall have to do it, if no one else volunteers, somewhere in that vicinity. Be of good cheer, my friend, and let the bees come—the more the better, and we will pay all expense and trouble they make.

HUMBUGS AND SWINDLES

PERTAINING TO BEE CULTURE.

We respectfully solicit the aid of our friends in conducting this department, and would consider it a favor to have them send us all circulars that have a deceptive appearance. The greatest care will be at all times maintained to prevent injustice being done any one.

THE GOLDEN BEE-HIVE, AGAIN.

THE "Golden" bee-hive agents are canvassing Breckenridge and adjoining counties, selling rights for districts and counties at terrible rates. One Charles Hardaway, of Breckenridge, gave $300 for a right for a very small district. I do not know the traveling agent's name, but will find out. I understand that there is one A. J. Carman, of Connecticut, with them. Said Carman is paid a salary of $2.00 per day to canvass the county. Will you please post me in regard to the hives and patents? If you have had any deal with A. J. Carman, please report to me. I think we had better have some advertisements struck off in large letters, to post up, in order to guard honest bee-keepers against such swindlers. H. W. CARMAN.

Custer, Beckenridge Co., Ky., May 11, 1886.

Friend C., we know nothing of the parties you mention. The Golden bee-hive has been for years used as a medium for frauds. I do not think it worth while to inquire whether there is a valid patent on it or not, for it is quite certain that no intelligent bee-keeper wants any such arrangement. I would advise bee-keepers to have nothing to do with any man who comes along wanting to sell rights for a bee-hive or any thing else; and in most localities the whole business has been recognized as behind the times, and beneath the notice of any intelligent man who reads the papers.

FRIEND PORTER'S REPORT.

CAPPING COMB HONEY WITH YELLOW WAX; QUEENS DEAD IN THEIR CELLS, ETC.

REPORTS from Virginia as to honey are not encouraging. With a very fine growing season, there is not the usual secretion of nectar, and the honey-crop will be light. Fruit-bloom and locust were very abundant, the latter always indicating a fruitful year. Fruit of all kinds promises to be abundant, and we are now shipping cherries to New York.

Last year I was annoyed to find some of my best colonies capping all their section-honey with yellow wax, as bright as new foundation. What is the cause? It was not pollen-stain, and as others at the same time were capping with white wax, it could not be the quality of nectar that developed the yellow wax. I should like to ask if any others have had such experience. I conclude it is a trait that certain bees may possess, just as some do that of sealing without an air-chamber under cap, which causes the dark appearance of some combs.

A peculiarity of this season here, is the failure of queen-cells. Never before have I seen so many dead in their cells. Scores of full-grown larvæ in capped cells have been found dead, and all were developed under the swarming impulse. I have examined many hives after first swarms have issued, and found perfect cells with lifeless queens. Can any one give a reasonable hypothesis? I know of no unusual electrical conditions. The colonies were very strong. Two young swarms, after hiving, have been found queenless. This may have been accidental; but the same causes that destroyed life, may have weakened the vitality of the hatched queens.

Blue thistle is now coming into bloom, and is a valuable honey-resource here. Red clover is always very abundant, and we await the development of the "clover apis" with much interest.

J. W. PORTER.

Charlottesville, Va., June 2, 1886.

Friend P., I do not know that I ever before heard of a yellow capping to comb honey. I am inclined to think the trouble with your queens is only accidental, and that it will right itself very soon. If it should be some malady it would be a rather sad case; but we trust not, however.

CARD OF THANKS FROM MR. HEDDON.

FRIEND H. TELLS US HOW IT AFFECTED HIM WHEN HE FOUND HIMSELF PICTORIALLY EXHIBITED.

MY surprise on opening the June 1st number of GLEANINGS can be better imagined than told. I little expected to find myself so conspicuously and pictorially exhibited, or to read the kind and too flattering things written about me by my biographer, Prof. Cook. It would be the worst kind of affectation to pretend that I am indifferent to the honor done me by friend Root, or untouched by the generous things said of me and mine by friend Cook. I most sincerely thank them both; and while I honestly say I have tried to be and to do what the biography gives me credit for, I am but too conscious of having come far short of my ideal. It will be my aim in the future more faithfully to realize that ideal, more fully to deserve the esteem of my friends, and more efficiently to labor for the advancement of apiculture. The tokens of respect and appreciation which I have received will not fail to have an influence in spurring me on toward the attainment of these ends. JAMES HEDDON.

Dowagiac, Mich., June 4, 1886.

DETERMINING THE SEX OF THE EGG.

ALSO SOME OTHER MATTERS.

COOK, Hayhurst, and others have much to say about queens laying eggs in shallow cells, and cite this as evidence that it does not require worker-cells to produce worker-bees. Now, is there any truth in this? and who is the author of the theory that eggs laid by the queen while she is in a horizontal position with the foundation, impregnates the egg by curving the lower part of her abdomen in such a manner as to bring her spermatheca in the right place to distribute the spermatozoid on the egg in the same way as it is done when laying in a contracted cell?

DO BEES HEAR?

If Marshall Darling, on page 269, had suspended his hives in mid-air, would blasting rocks disturb them? I think that bees do not hear, except by the jarring of their antennæ while they are at rest on or touch something solid.

CAN WE USE WIRE CLOTH OVER THE GRATE OF A SMOKER?

D. McKenzie's fire among his hives, page 268, reminds me of the caution that is required in using a smoker while manipulating hives that are filled with chaff. I protect my smoker by a piece of wire cloth bent over the grate. You will have to take the grate out of the smoker to do this. Bend a piece of wire cloth a little larger than and the same shape of the grate over the grate, and drive it back in its place again. Can't the smokers be fixed in some such way as this before sending them out? We always want to have things safe.

HOW MUCH MOISTURE CONDENSES IN A COLONY DURING WINTER?

I have 40 colonies wintered in good shape in single-wall hives, size 18½×18½ inside, with an upper story filled with leaves. There were leaves also on each side of five to seven frames of bees and honey, separated by two thin (1-in.) empty division-boards. The portico in front was likewise filled with leaves. Between two projecting boards that I have hinged to the back of the hive (used for a comb-holder in summer and for this purpose in winter) I filled with leaves, and covered with my entrance-board one foot wide,made out of clapboards. The cover of the hive is made from clapboards, and shaped like the gable roof of a house. On the inside of one of these covers I tacked last fall a large piece of enameled cloth, having it flap on to the leaves in the upper story in such a manner as to catch the water that would condense on this cloth, and drip down into a cavity made for the purpose. I collected nearly a gill of water in this way in a week's time; then I let it remain through the winter, and in March the combs in this hive were covered with mold, and sugared (away from where the bees were clustered) so badly that the bees would starve before they could eat it; so I am satisfied that, if dampness does not hurt the bees, it injures the honey. This water must have run off from this enameled cloth. The hives were ventilated like yours.

J. L. HYDE, 40—40.

Pomfret Landing, Conn., April 5, 1886.

Friend H., I never heard of the theory you suggest, in regard to the queen being in a horizontal position.—In regard to the bees hearing, the experiment I mentioned, of the teeting of the queen while on a comb held in the hand, seems to me touches the point. The bees will hear the note of the queen when the combs are out of the hive, and I don't think that any jar could be communicated while the comb is held in the hand.—Our smokers were first made with wire cloth instead of perforated tin; but it filled up and clogged so badly that we made a series of experiments with tin having different sizes of perforations. Those we now use give by far the best results in the long run.—I am well aware that a large amount of moisture is given off by a colony of bees in the winter time.

A LESSON DRAWN FROM THE HABITS OF BEES.

YOUNG MAN, DON'T "GO WEST."

FRIEND ROOT:—The honey season has opened up unusually well here. Fruit-bloom was very abundant, followed by white clover. Lower stories are now full. I shall commence extracting at once. My bees are mixed—Italian, hybrid, and blacks—as well as some large brown or gray bees. None of them are purely American, judging from their habits, not having any respect for the Sabbath; they work, swarm, and act as badly on Sunday as on any other day. Yet there is *one* American trait; i. e., a desire to "go west." Several colonies of mine have left a good new Simplicity home for a dug-out, or hollow tree, until we adopted your plan of giving the new colony a comb of unsealed brood from the parent, or some other colony. I find it works like a charm—contented, they at once commence work.

The thought occurred to me, could we not cut off a slice or two of the home farm for our boys when they swarm, and have them settle near us, where the country is settled—school and church buildings already built; society, and home comforts to keep their hearts warm, and social ties unsevered? Our farms are too large for the necessary high state of cultivation they demand and must receive, if farming is made to pay.

The western fever is raging all over our land. Many go, while *few* are benefited by it greatly. The loss of time, and expense of moving, together with the cost of one year's supplies necessary in a new country, if added to the "one frame" from the old colony, would build up a home away from the privations of a frontier life. Yet bees will swarm, and occasionally run away. Young people will, may, and do "go west to grow up with the country," and we must accept the change as one of the unavoidables of life. Yet when we see the young man who was raised in refined society, with his wife, the frail, fragile daughter of a cultured home, braving the trials of a new country, living in a dug-out on a treeless prairie, beneath the scorching rays of the sun, breathing the heated air from the broad prairie, cooking their food, and warming in winter their dug-out with hay or cow-chips for fuel, drinking alkaline water, vainly endeavoring to be happy in the thought that, in after years, they'll own a quarter-section, I think how much more happiness in a ten-acre lot, back in civilized life—a home, purchased and made like a little corner cut out of paradise, with no more cost than has been expended in going west and one year's living. There is not a single State in the Union west of the Alleghenies, that is one-half developed yet. Young man, remain where you are, and assist in developing your native State. "Make not haste to get rich," but, rather, enjoy life as you go along.

Ramsay, Ill., June 7, 1886. L. F. STODDARD.

Friend S., I agree with you exactly, and I am abundantly satisfied that there is a field wide enough for all who care to explore it in developing the latent resources of a little patch of ground; the new agriculture, for instance, and the possibilities that are opening out through the modern system of market gardening. Our new-agriculture beds are now furnishing green peas, new potatoes, beets, and lettuce, in great abundance, and, most of all, these things are grown without the aid of glass at all. Peas sown in February now yield three good pickings, and they were never covered, even one night. —Now, in regard to going west, I suppose the same rules would apply in a measure out west that apply here, only this must be considered: If you want to get good prices for your stuff after it is raised, you must have a thickly settled community, or else be in the immediate proximity of villages, towns, and cities. To get good prices you need to be in a climate where frosts and snow prevail, or where severe drouths are common. Strange, isn't it, that a locality where unseasonable frosts and drouths are prevalent is the one to make money? But so it is. The educated and up-with-the-times cultivator of the soil will have good crops any way; and where almost everybody fails in common slip-shop culture, there will the progressive man get rich. Again, this bright Monday, June 14, a dozen boys and girls are picking strawberries. On one patch, where so much manure was put on that everybody said I would never get my money back in the world, they are getting enormous berries in enormous quantities. The pickers are happy, the men who are selling the berries from the wagon are happy, and our customers are happy; and it all came about by fixing a little spot of ground thoroughly.

HONEY-PLANTS OF TEXAS.

ALSO VARIOUS OTHER MATTERS.

I SEND you a resurrection plant like the one described by the little girl on page 417. It is from Monterey, Mexico, but is quite common along the Rio Grande, in Texas, and is no novelty here. This one has been out of the water about six weeks. I think the plant will grow after being out of water for a long time, but just how long I do not know. It is sometimes called the "rose of Jericho;" but according to an article recorded in one of our agricultural papers several years ago, it is quite another plant.

I also send you a specimen of another shrub for naming. It is plentiful in some localities. It grows to the height of 6 or 8 feet, and one to two inches in diameter near the ground. I think it of considerable value for bees, as it is not affected by the drought. The disk of each of the little flowers is covered with honey, which can be both seen and tasted. It is swarming with bees at the present time. One thing that is perhaps against it is, that the honey is so easy of access that it is visited by wasps, flies, and all kinds of insects; but the leaves seem to be free from lice and other parasites.

Not long since I noticed the bees working on honey-locust. There were literally thousands of them. Is the honey-locust considered of much value? The mesquite, which predominates throughout Western Texas, is valued highly by some bee-keepers, but the yield of honey is uncertain, though it usually blooms two or three times during the summer. The cat-claw, another of the same family, is also highly prized, and the yield of honey more reliable, but I do not like the flavor.

It is very difficult to ascertain the proper name of any plant or tree here, as the names are derived from the Mexicans, who call every thing "chaparal," meaning brush.

Some years ago I saw what was called a petrified wasps'-nest, and it very much resembled what it was claimed to be.

I have heard of a great many attempts being made to steal honey, but the thieves invariably left behind evidences that they were not skilled in handling bees. Do you think a true lover of bees would be guilty of such an act?

Wild sunflowers, some of them nearly as large as the cultivated varieties of the North, are very abundant here, but I do not see many bees working on them.

In one of my colonies a large number of the young bees have defective wings, and perhaps a dozen perish before the hive every evening. I hear the same complaint from others. What is the cause?

On page 401, Mr. Doolittle tells how he strengthens weak colonies. Would not this be a reliable way of introducing queens?

I have one serious objection to offer to GLEANINGS. That is, it does not come often enough. I would rather have it half the size and every week, at a little advance in price.

The outlook for honey is very discouraging at present. Bees are at a standstill, with but little disposition to swarm. It is unusually dry for this season of the year. T. F. MCCAMANT.

San Antonio, Texas, June 1, 1886.

Thanks for the resurrection plant, friend M. We are going to try to see if we can not make it grow in *real earnest* as well as to *seem* like growing. The other plant you send is different from any thing heretofore submitted. We have sent it to our botanists to name.—The defective wings you mention, I think are caused by the ravages of the moth-worm.—The plan you mention for strengthening weak colonies is sometimes used for introducing queens, and probably succeeds as well as any other way, but it is a little more trouble.

WHAT AILS THE BEES?

MORE ABOUT THE COLONY THAT REFUSED TO ACCEPT THE QUEENS.

On page 350, GLEANINGS for May 1, I gave an account of some queer actions of a colony that was supposed to be queenless. You, friend Root, ask if there was any trouble in their caring for their brood, feeding the larvæ, etc., to which I answer, no. The frame of eggs and larvæ given them was properly cared for, but no queen-cells were started, although the frame remained until it was past being used for that purpose. You say, friend Root, that you are still inclined to think they had some sort of a bee in the hive which they regarded as a queen. In my experience, where such a state of things exists the bee that was accepted as a queen nearly always lays eggs of *some* kind; and then, again, what became of this bee? They had a fair chance to start cells this spring, but refused to do it, but accepted this queen, and have built up surprisingly; so at this date, May 24, 8 frames are covered with bees, and 6 of them fairly filled with brood; and, again, in regard to the age of those bees I will say I have not a colony in my yard out of 70 where the old bees held out so well. Now, it would, in this case, seem that it was not necessary to have young bees for winter, and I have had several cases that pointed that way, while I have always thought, reasoning from the length of a bee's life, that young bees must be best; but this, however, goes in favor of friend Heddon's theory of old bees for winter.

I have another strange puzzle in bees. Although I have kept bees in frame hives, and read the bee-journals ever since the *A. B. J.* was born, I have never seen nor read of an account of a case like the following:

Saturday last I went to visit a bee keeping friend who has a colony of bees in a log sawed off about 3 feet long, and set on a bottom-board. All is neatly painted, with surplus case on top, from which more or less surplus has been taken for the last 7 years, the colony always coming out in good condition. There is plenty of sealed honey in the top of the log, in sight, and there is, without doubt, 40 or 50 lbs. in the log. This colony came out this spring, strong in bees, and every thing looked prosperous until 7 days before I was there, when the owner thought by appearances that some colony was robbing them. They came out in large numbers, and seemed to be trying to carry off some very small, inferior bees that looked like some very old shiny robbers, only that they appeared sick from that time until I was there. For 7 days an average of a quart a day, according to the judgment of the owner, crawled out and died. I turned the log up and examined them, even breaking out some comb, and found brood in all stages, from the egg to the hatching bee, and in apparently a healthy state. I reached clear down to the bottom, but these little inferior black shiny bees, hardly looking like a honey-bee, are all scattered through the hive in a dying condition, as is also the larger part of the bees, both old and young. They crawl over the combs with a trembling and staggering appearance, with their tongues run out, and helpless, so the tongue will not move, and they keep crawling out on to the front board, and roll over on their backs and kick awhile and die. I have sent some of the bees to Professor Cook, to see what state he finds them in. If any one has had any thing of the kind, or can tell what is the matter with that colony of bees, I should like to know it. J. B. MASON.

Mechanic Falls, Maine, May 24, 1886.

Friend M., from your description I think that your bees have the nameless bee-disease which has been so much talked about of late. Give them a new queen, and the bees will be all right, unless I am mistaken.

BOOK-REVIEW DEPARTMENT.

HOW TO RAISE COMB HONEY, AS PRACTICED BY OLIVER FOSTER.

WHENEVER we see any thing from the pen of Oliver Foster we naturally conclude that he has something practical to present, and something worth saying. We are not disappointed upon reading his little work upon "How to Raise Comb Honey." It is published in pamphlet form, of only 16 pages, but there is a good deal there. Among the first things he discusses is, "What Hive is Best?" In answer to this question he thinks the hive that has given the most general satisfaction is the one given us by father Langstroth, as well as the modified froms, including the Simplicity. The style of hive he uses he thinks is simpler than the Simplicity. The beveled edges between the cover and body of the latter he regards as unnecessary for protection against storms. His hive, accordingly, has the top and bottom edges cut square. In other respects his hive is essentially the same as the Simplicity, with the exception of a little device for holding down one end of the frames, to facilitate the removal of the upper story.

SECTIONS OPEN ON ALL SIDES.

The writer, after giving his preference decidedly in favor of the pound section, urges, as a great improvement, that the sections be open or accessible to the bees from all sides. As he is probably the first one to originate and put in practice this idea, perhaps the arguments are best expressed in his own words:

> In using section boxes, we think some important points have been overlooked. Every available inducement should be used to inspire prompt, constant, and energetic work in the boxes until they are finished. In fact, we should *create a passion* for putting honey in boxes. This requires no magic. To accomplish it there should be no separation between the sections, and as little as possible between them and the brood. There should be *free communication* between the sections in *every direction.* They should have deep slots on all 8 edges. You may not appreciate the importance of this until you have tried them. When we take into consideration that the object on the part of the bees in storing up honey in summer is to have it accessible for winter consumption, and that in winter the bees collect in a round ball, as nearly as possible in a semi-torpid state with but little if any motion, except that gradual moving of bees from the center to the surface and from the surface to the center of this ball, we may imagine how unwelcome it is to them to be obliged to divide their stores between four separate apartments, each of which is four inches square and twelve inches long, with no communication between these apartments.
>
> Another important object is secured by using open-end sections. Bees are much more apt to build the combs out solid to the end and bottom bars of the sections, if there is comb attached just the other side, with no bee-space between, but with a wide opening through. Honey will not ship safely, nor sell well, unless thus built out. Also, these open-

> ings on all sides serve as a guide to insure straight combs.
>
> Strenuous efforts are now being made to get all the honey stored in the sections and none in the brood-nest. While we would not advise the practice of this with a view to feeding sugar for winter stores, still it is an acquisition to be able to get a colony to put *all* their honey in the sections *while they are at it.*
>
> Some unnatural operations are being resorted to, to *discourage* the deposit of honey in the brood-chamber, such as contracting or inverting that apartment. While this plan has its advantages, and may succeed, we would accomplish our object by milder means. If the foregoing and the following conditions are observed, bees will store their honey in the boxes, and not below.

It is to be observed from the foregoing, that Mr. Foster does not recommend inverting to bring the brood next to the surplus-apartment. He advocates, instead, putting the crate of sections on the hive when the honey begins to yield, or at the time when the brood-chamber is full of brood, and with but little honey. The brood is thus brought close to the surplus-apartment. This, Mr. Foster claims, brings about the same results as inverting.

FOSTER'S ADJUSTABLE CASE.

This is quite an ingenious contrivance, which, if I am correct, accomplishes about the same result as Heddon's new surplus-arrangement, but in a different way. Briefly, it is simply an oblong box or tray without bottom, of nearly the depth for sections. Two of its diagonally opposite corners are made separable, while the other two corners are fastened permanently. The case, when laid upon a flat surface, can be enlarged or drawn out, thus greatly facilitating the putting in and taking out of sections. The latter can be arranged in the case carelessly, and then be quickly drawn into position by sliding together the two pairs of L-shaped sides. An iron clamp, which Mr. Foster has devised for the purpose, is adjusted over the case. The two L-shaped pair of sides, as well as the sections which they inclose, are firmly and compactly pressed together. A pair of very simple and ingenious wedge-shaped pieces of tin now hold the whole in position, when the iron clamp, before mentioned, is removed. The sections are so compactly compressed together that the crevices between the sections are closed, preventing, to a large extent, the soiling of the edges of the pound boxes with bee-glue. This takes advantage of the fact that bees seem to abhor a crevice, and so fill it with propolis. Another advantage is, that the mere tension of the case holds the sections in position, rendering a bottom unnecessary, so that the case can easily be inverted if desired. When placed upon the hive it rests upon a slotted honey-board, the strips of which correspond to the bottoms of the sections, thus preventing the under sides of the sections from being soiled by the bees. When the case of sections is filled it is taken off the hive and laid upon a level surface, and the adjustable sides drawn apart. The filled sections can easily be taken out without prying with a knife or screw-driver to get the first section out.

The foregoing are, in brief, the advantages claimed by the author, and it seems to me we have all got to adopt some such surplus-arrangement as this or something similar, sooner or later. There is only one objection I would urge: If it is not made perfectly true to measurement, or if the sections are not of the right width, either from shrinkage or bad workmanship, we should be likely to have trouble. Perhaps the inventor does not find this an objection after all, as he has used it two seasons.

There are a number of other valuable hints in this little work, and I feel assured the reader will be well repaid if he will read it carefully. I do not know the price of the work, but I presume it can be obtained for a small amount, of the writer, Mr. Oliver Foster, Mt. Vernon, Ia. **ERNEST.**

MAKING FOUNDATION.

ORDERING QUEENS FROM THE SOUTH, ETC.

FRIEND ROOT:—I want to tell you that I have never bought an implement which has pleased me more than the comb-foundation mill I ordered of you. Yesterday we made our first run of fdn., and everybody on the place was smiling nearly all day. Every little while some one was saying, "Oh! isn't that nice?" I had just been buying up all the beeswax I could hear of for sale until I had so much on hand that it looked almost *reckless;* and my neighbors wondered what in the world I wanted with so much; and, in fact, I began to think may be I *had* better stop buying, until I was sure I could make good fdn. I am just more than pleased now. As I have used fdn. of the different makes for 8 years, I think I *know* what good fdn. is, and am not satisfied with any except the *best.*

Many thanks for the queen you sent on the 12th inst., to replace one that was lost in the mail, sent the 28th of April. The directions were printed on the cage as plain as could be, and yet they were missent, and were out some 18 or 20 days; and when they did come, of course were all dead. But this is the first queen I ever lost or had delayed through the mails.

Bees are stronger for this date than I ever before knew in this latitude. Fruit-bloom was quite good. By the way, how many of our bee-keepers appreciate the value of the white willow (or fence willow)? I have some 400 rods of it here on my farm, and there is plenty more all over this country; and when it came out in bloom it reminded me of basswood time. It is now the third year that my bees have done exceedingly well on it (before that I had not noticed it so closely).

I don't wish to complain; but what success, I wonder, have other parties had in getting queens from the South *early.* Out of five ordered and specially desired early (to give to queenless colonies early in the spring) from different parties and at different seasons, I have never yet received *one* any sooner than I could have *raised* them or got them from parties in the latitude in which I live. Now, this is quite an item to me, for I had thought, "How nice this is, when we find a colony queenless in early spring! Why, all there is to do, just inclose $1.00 to some queen-raiser away down South, and in a few days we can have that colony all right;" but with my past experience I shall have to modify my expectations in that direction. This spring I ordered of an extensive breeder in the South, requesting him to put with the queens an extra number of bees, and send as soon as possible (the order was sent April 13). After waiting some ten days, and looking for the queens, I received a note, thanking me for order, and stating that as soon as the weather would do to risk sending them he would ship, etc. We were having 60 to 75° in the shade at the time, quite a number of days, and the nights were nice and warm. I told him to please hurry them on, etc. The queens finally came May 10th, when I had plenty of drones flying, and could have just as well raised some fine queens myself in the same length of time. If my experience is the exception, and not the rule, I shall probably try again, some time. But if this thing is quite common, and if it is not safe to ship queens in early April as far north as Central Iowa, I should like to be enlightened, and will be governed accordingly.

D. E. BRUBAKER.

Maxwell, Story Co., Ia., May 22, 1886.

We are very glad the mill pleases you, friend B. Now, is not part of it owing to the fact that you were in just the right shape to be pleased? I agree with you in regard to getting early queens from the South; that is, there seems to be some truth in what you say. With all their great advantages of climate, they don't seem to get very much ahead of us after all, if we should set right down and try hard. You know I have for several years proposed to give advertisements free to all those in the South who had queens on hand ready to ship during the month of April. Very few have responded; but probably those who did respond were very quickly sold out.

LETTER FROM BRAZIL.

FUEL FOR SMOKERS, ETC.

MR. ROOT:—I am much obliged for your recipe for vinegar. If you think it of some utility for your readers I will with pleasure give you two hints, perhaps of some use.

The first is a fuel for smokers, the best I ever tried, and perhaps at hand with your Southern friends. It is the pith-tree (aloes), in pieces not very small. When dry, it burns exceedingly well, gives plenty of smoke, and no sparks.

A TWO-STORY HIVE THAT WILL ADMIT OF RAISING THE LOWER FRAMES WITHOUT REMOVING THE UPPER STORY.

The second hint is a hive I have been trying for six months, very successfully. I like Simplicity hives; but I prefer two stories, even for extracting, but find quite an annoyance (the separated second story) in the handling of which bees are often killed. I have profited by the unwillingness of bees to build comb in narrow spaces. I make a sufficiently high box with two thicknesses. The under frames are put as in ordinary hives, the upward stand parallel to the first; only their sides are half an inch or ¾ from the hive, instead of the usual distance. Two detachable pieces of wood lying on nails support the upper frames and division-boards. If you keep always one or two *empty* frames in the upper story, there is no fear of building combs off the frames.

MIGUEL RIBEIRO LISBOA.

Barbacena, Brazil, S. A., Apr. 26, 1886.

Thank you, friend L., for your kind letter and suggestions. The arrangement you mention for the Simplicity hive has already been in use with us; but as it has been dropped for some years, I am inclined to think it has not been found to be very satisfactory. We shall be very glad indeed to hear something more about the bees and bee culture in your far-away climate.

POPLAR HONEY PREFERRED.

ARE THE CARNIOLANS SUPERIOR TO ITALIANS?

THOUGH not strictly an A B C scholar, not having your text-book, but Cook and Langstroth, I have, for forty years, been an occasional student of bees. Every little while some new fact proves to me that I have not yet "learned it all." In so long a time I have had to do more or less with many strains of bees. My earliest experiences were with pure Germans, which were not hard to handle. A few that I have handled in late years were almost, perhaps perfectly, pure Italians, but the great majority have been Italian hybrids of varying shades of impurity.

Some of these have not at all maintained the reputation of hybrids for crossness, but the majority of my present stock, all mixed, are beyond comparison the most vicious bees I ever handled. They seem at least reasonably hardy, for all my thirteen colonies wintered in plain Gallup hives, on summer stands, and almost exclusively on the aster honey which they gathered last fall.

My vicious bees average passably as honey-gatherers. The crossest colonies are generally the best workers. A few days ago we extracted ten gallons of extra-fine well-ripened poplar (tulip-tree) honey! One of your contributors complains of no market for it, on account of its dark color. Most people here prefer it to any other kind produced in this vicinity, though my own choice is the sourwood which comes later. We keep our bees here exclusively on natural stores whenever they gather enough after the last extracting, and then we never have trouble with diarrhea or dysentery, probably because our bees are seldom confined 30 days at once, and because our severest cold spells are of short duration. Almost the only sources of loss are freezing and starvation.

As a source of honey-supply, white clover here seems almost worthless. It makes the best show in the poplar season, when bees will hardly touch any thing but the great tulip-blossoms of that rich honey-bearer. Just here we have not a great deal of it; but my former near neighbor, J. F. Montgomery, lives now about a dozen miles away, where, last May, great fields were white with white clover, and he says that he never gets any appreciable quantity of white-clover honey. We find that Italians and hybrids work far more on red clover, especially the "sapling," or "peavine" variety.

WHY DID THE QUEEN SUDDENLY STOP LAYING?

A few weeks ago I procured some eggs from one of Mr. Montgomery's best queens, hoping to make my stock both more amiable and more industrious. Though some of my queens were lost in introducing, I now have several busy laying. But my particular puzzle is one that is not laying. I released her from a cell partly destroyed by a rival, and introduced her to an artificial colony, formed about twelve hours before, of frames and bees from three or four colonies. She was accepted, and a week later had nearly four frames full of eggs and young brood, and her abdomen was considerably enlarged. Four days later not an egg or an unsealed larva could be found in the hive. Not seeing the queen, I feared that too much meddling had caused the bees to destroy her and her progeny; so I gave them a frame with brood and eggs, and for about a week I left them undisturbed. At my next inspection that brood was nicely sealed; no royal cells were started, but the queen herself, a little reduced in size, was moving about quite lively, and not an egg could be discovered. Can you explain these eccentricities?

Can any practical bee-keeper, one who is more interested in honey-production than in the sale of novelties, answer a few questions about Carniolans? Are they equal to Italians in hardiness? in fecundity? in protecting themselves against moths and robbers? in honey-gathering? Are they superior to them in gentleness? Are their hybrids gentler than Italian hybrids? This last is of some importance in this neighborhood, where blacks and mongrels abound. 8—David Strang, 13—13.

Lincoln, Lincoln Co., Tenn., May 24, 1886.

Friend S., I do not know any reason why your queen stopped laying so suddenly, unless she has failed and will soon be superseded. If the yield of honey stopped just about the time she stopped laying, that might account for it; but they seldom stop all at once, as in the case mentioned.—Our experience with the Carniolans does not warrant us in calling them any thing better than Italians. They are rather gentler to handle than the average run of hybrids, but we can not find that they are any more so than full-blood Italians in general. In other respects they are just about like Italians —we can not discover any difference worth noticing. See Our Own Apiary, this issue.

SAFE INTRODUCTION OF QUEEN-CELLS.

AN INVENTION THAT SEEMS TO PROMISE A GREAT DEAL.

Friends Root, Hutchinson, and others, have told us in the past how they took a laying queen from a nucleus or full colony of bees, and immediately (before closing the hive) gave the bees a nearly mature queen-cell, they having little or no trouble regarding the bees destroying such cell, any more than they did to wait 48 hours before giving such cell, as most of the bee-keepers of the world are obliged to do, if they would be at all certain of success. If I remember correctly, Mrs. Harrison said she could not succeed with more than one cell out of twenty by this plan; and my failures were still greater than hers, for I do not now remember of ever getting more than one cell accepted, where said cell was put in within six hours after the removal of the queen. In fact, I have so utterly failed that I had become a little skeptical, classing such stories of success along with the stories of successful artificial fertilization of queens.

Well, the time having again arrived when I desired making the most possible out of the nuclei I had formed, this subject of immediate introduction of queen-cells and virgin queens came up in my mind. It was evening, and I had lopped down on the couch waiting for the return of a part of the family, and thinking what I could do regarding this matter. In a half-dreamy sort of way I wandered over the past and thought that my only plan of success had been by the one friend Root had given, of putting a square wire-cloth cage over a cell, and pressing the cage into the comb, thus keeping the bees from the cell for two or three days; but as the bees often ate under this cage and thwarted my plans, I felt that it was little in advance of wasting 48 hours. While these thoughts were in my mind I fell asleep for a short period. When I awoke, instantly the thought came to me to go and make a small funnel-shaped cage of wire cloth, just large enough to hold a queen-cell, and I was master of the situation. I at once made a round V-shaped stick, and taking a small square piece of wire cloth, rolled it around the stick in such a way that the hole in the small end of my wire-cloth funnel was as large as a lead-pencil. I next cut off a piece of a ⅝-inch cork and placed it in the large end when my cage was ready.

The next day I was to send off some queens; and as I had a lot of cells ready to hatch the day after, I had only to wait during the night before I could try my plan. Accordingly, as soon as I took the queen out the next day to ship away, I went and got one of my nearly mature queen-cells, slipped it in my cage, with the point down into the lead-pencil hole as far as it would go, put in the piece of cork, ran a small wire through the meshes of the cage above the cork, so as to keep the cork in, and at the same time make a handle to hold the cage in any position I wished it among the bees, when the wire was bent so as to hook over the top of the frames, and the caged cell hung in the hive. More were treated the same way, for some way I felt confident that the plan would succeed.

I was now called away from home for two days, and upon my return I found that, in each hive having a caged cell, there was a nice virgin queen; while in a few hives in which I had put some of the same cells without caging, all were destroyed. I have now used this plan for two weeks, and in not a single instance have I failed of having the cells hatch all right, and the bees accept the queen. The plan also gives you the privilege of placing the cell right in the center of the smallest cluster of bees without cutting or mutilating the comb, as must of necessity be done by the old plan in these little colonies during cool weather, which is no small item with those desiring perfect combs. I suppose I might have waited before giving this plan to the reader, till I had tried it through one season; but when I thought of how I had been bothered for years, and of the little expense required for all to test it, I concluded that I would not wait; for if it worked with all as it did with me it would save many queens for the bee-fraternity. The principle of the plan is this: The bees always destroy a cell from the side or base, and never at the point. The cage protects the cell everywhere except at the point, but still allows the bees to get accustomed to the presence of the cell, the same as if the cage were not there. The lead-pencil hole allows the queen to hatch, the same as she would if the cell were not caged, while the bees can feed her and hold her in the cell as long as they please, so that she can not get out till they are ready to accept her.

G. M. Doolittle.

Borodino, N. Y., June 1, 1886.

Friend D., I suppose you know the idea of caging queen-cells is not new. Cages specially adapted for this purpose have been advertised for a good many years. There is one point in your invention, however, that seems to be new, and that is, leaving an opening in the apex of the cone, large enough for the young queen to bite her way out. The wire-cloth cones used by friend

Alley and others in their drone-traps I think will answer the purpose nicely. We will give it a trial at once, and report.

PLANT-LICE AND HONEY-DEW, AGAIN.

SOME OBSERVATIONS BY MRS. CHADDOCK.

I WONDER if these lice on our box-elder are the kind of lice that make the honey-dew. There are millions of them on the under side of the leaves and along the stems, packed tightly on top of each other. To the naked eye they are a little green bug, varying in size from a grain of mustard to a tongue-grass seed. Under the microscope they are a pale-green, waxy-looking affair, with deep-green stripes down each side of the back. Their legs and feelers look as though they were made of white wax, tipped with reddish brown. The eyes are of the same color as the tips of the legs and feelers. They are fat and squabby, and when they walk the body drags. When they get older they have long white wings, and the body is not so large. They have a sort of a *skeater-did* appearance. They taste like the leaf that they feed on (I ate a few), and just now I found out that the top of the leaf is all glistening with little splotches of a decidedly sweet substance. Under the magnifier it looks like clear water, not standing in drops, but flattened out or smeared over. I pressed the bugs under the lens with a pen-point, and they gave out a tiny drop, too small for the naked eye to see, and I tried to taste it, but it doesn't make any impression on the tongue, so of course they are the very bugs that make the honey-dew. I had not seen the sweet stuff on the leaves when I began writing. The bees are not working on it at all, as the apple-trees are in bloom.

MORE HONEY-DEW—LATER.

For a whole week my bees have been roaring about the tops of the Norway spruce, and I have been wondering what they found there, but had no time to climb the trees, and I could see nothing on the lower limbs. But this morning after I had turned the cheese, fixed the fire under the soap-kettle, put more water under the lye-hopper, milked two cows, and fixed the churn, I built a sort of scaffold out of a tub, a box, a board, and another tub, and, standing up there, I found drops of nectar (?) in among the new growths. It is as clear as water, and *very* sweet. Along the stem were some things that looked like brown scales; but under the magnifier they developed into plant-lice. They resemble the insects found on the box-elder, in every thing but color, these being of a yellowish-brown color, with darker brown stripes down each side of the back; and when I pressed them they discharged (I should think) six times as much sweet as the green kind did. So far I am pleased with them. This is a dry time for honey here; and if the plant-lice will be kind enough to fill the gap between fruit-blossoms (apple-blossom) and raspberry-bloom, it seems to me that they will fill a great vacancy. Perhaps if each one of these lice is to be the parent of a million more I may get over my joy of them before the season is over; but just now I'm pleased.

My bees have gone crazy. March hares, loons, and all the other comparatively crazy things are safe and sound when compared with my bees. They don't know what they don't want. Always, till this year, I had my bees scattered about under the maple-trees, on the north side of every thing, and in corners here and there. I always keep the queens' wings clipped, and when they swarm I catch the queen, put her under a goblet on a plate, set her in the shade, and let the bees come back at their leisure. I used to carry the old hive away and put the new one in its place; now I turn it around, *a la* Heddon, and set the new one where the old one used to be. I always put in a frame of hatching brood, and never had bees desert the hive. Now I have my colonies all in one spot, standing eight feet apart each way. When the first swarm came out I proceeded just as I always had done, but the bees came back and divided themselves around among the four hives that were nearest. Then another swarm came out, and they were going to do the same, but I put fifteen yards of cheese-cloth around one hive, a bolt of muslin around another, a table-cloth on the third, and a wet towel on the fourth. Then I lighted up my Clark's smoker; and wherever they seemed thickest, there I was in their midst. I finally persuaded them to go back where they came from; and when I had time to draw my breath and fan myself a little with a rhubarb leaf, I began to smell smoke, and there the cheese-cloth and the table-cloth were both burning away. I subdued the fire, and then another swarm came out, and, without ever alighting, or acting in any way as bees should, they went over to a colony that was already boiling over full, and went in and on the hive.

The next day was Sunday, and Sunday is always a field day with my bees. The one that went in the empty hive the day before came out and alighted on an early Richmond cherry-tree. I caught the queen, and we carried a hive over there and put the bees and queen in; then carried them off a distance from the rest, and left them, with no brood nor foundation in the hive. Two more swarms came off and came back when they ought to.

In the afternoon these two swarms came out and alighted on two barberry bushes that stand close together. One of them had just about settled when the other started out. Then when they started to go back, each one went to the wrong hive and went in and stayed all right. Next day they came out and both went in one hive, and all the other new swarms came out, and, after airing themselves for awhile, went back where they came from. Hatching brood doesn't make a particle of difference. The first swarm started 23 queen-cells in the 24 hours that it occupied the hive. None of the others started any. Now as to their being too warm. I hived them in Simplicity hives, and I set them twisted on the bottom-board so that the air could come in; then I put muslin on top of the frames, then I set an empty hive on top of that, and put on the cover so that the heated air could pass out. The hive that held the two swarms, I piled up four stories high, the two lower ones having frames. I don't mind a little skirmisking; but to have the bees playing "pussy wants a corner," trading hives with each other, coming out every day to take the fresh air, as if they were invalids, and the doctor had ordered it, and hanging on the outside of hives while billions of clover-blossoms are going unsucked, is too much. **MAHALA B. CHADDOCK.**

Vermont, Ill., May, 1886.

Why, Mrs. C., I do not wonder that you

thought your bees had gone crazy. Probably a great part of the trouble was caused by the change in the way you locate your hives. Why not divide them before they are ready to swarm, and not have any swarming? That is the way we do here; but then, we don't raise comb honey, you know. No wonder you wanted to sit down and fan yourself with a rhubarb leaf. Sometimes the bees seem to have a sort of mania when they first commence swarming in the spring; but I think if you keep patient you will find they will get over it and behave all right after a little.

MRS. HARRISON IN REGARD TO THE MISTAKES SHE HAS MADE.

SHALL BEES BE LET ALONE IN THE SPRING, OR SHALL THEY BE FUSSED WITH?

WHEN our little girl used to do any thing wrong she would say, "I made a mistaken;" and I have come to the conclusion, that I have made many "mistakens" in my spring management of bees. Last fall, when I fixed them up for their winter's rest I told them that I would not meddle with their household arrangements until after fruit-bloom, and I have kept my word to them in good faith. I laid some comb honey upon the frames of a few that seemed light when carried from the cellar, and fed in the open air all the odds and ends of honey that had accumulated in the honey-house during the winter. I always keep a regular feeding-ground in the same place, and I have never induced robbing by so doing.

One spring, following severe winter losses, I tried to follow Mr. Doolittle, and I am confident I destroyed many weak colonies that would have pulled through if I had let them alone. There are so many minor points and notes of warning that the successful ones fail to give in their *modus operandi*, that what is safe in their hands often proves a failure in the hands of others. Hereafter I shall do my *spring* work in the fall; i. e., I shall feed them if they need it, abundantly, tuck them up snug and warm, and let them manage their own affairs until after fruit-bloom. I have had less balling of queens, swarming out, etc., this season than ever before, and they never so entirely alone paddled their own canoe. Clover is blooming, with very cool nights, and little honey coming in. It is very dry in this locality. Hives are running over with bees, but few swarms. MRS. L. HARRISON.

Peoria, Ill.

Mrs. H., I, too, have come to the conclusion that we did our bees a serious damage by cleaning out the hives, closing up the brood-chamber, and too much manipulation before the weather had got to be warm and settled. I have seen them swarm out just after their hives had been overhauled, when the bees that had not been tinkered with behaved themselves all right. Now, I suspect that the wisest way would be to give help when help is needed, and do it when the weather is suitable, but avoid any thing that demoralizes them or discourages them when they are first collecting their latent energies in the spring. For instance: If the queen should die during the winter, which often happens, the colony would be lost without attention; whereas it might be one of the best colonies, if given a queen in season, or sometimes if given only a frame of brood. The same in regard to stores.

NOTES FROM THE BANNER APIARY.

No. 78.

BENEFIT OF SPRING PACKING.

I TOOK the bees from the cellar the middle of April. It did seem foolish, during the warm days that succeeded, to pack the bees with chaff upon their summer stands; but I did it—*i. e.*, all except the two strongest colonies. At this writing, May 25, they have been unpacked a week, and it is easy to see that several of the packed colonies have outstripped the two left unprotected.

"A YEAR AMONG THE BEES."

This is the title of a bee-book by one of my best bee-friends, Dr. C. C. Miller. It has been said, that the sale of a book depends very much upon its title. If this is true, the doctor is to be congratulated, as "A Year Among the Bees" was very happily chosen to stand at the head of that delightful little narrative, descriptive of the apicultural journey of one year; a jaunt that we bee-keepers all take each year. "A Year Among the Bees"—how pat!

The doctor does not claim to have made any great discovery. He says: "At the risk of losing caste as a bee-keeper, I am obliged to confess that I never got up 'a hive of my own,' never even tried to plan one * * *" But I will tell you what he has done. He has removed from our path numberless small obstructions. He has smoothed our pathway, so to speak, and has done the work well. When traveling upon the highway it is no great annoyance to go around the hills, to turn aside for some large boulder; but the small stones and ruts in the roadbed are often quite trying to the temper. Great losses and disappointments are sometimes borne with greater equanimity than the petty annoyances and trials that come to us almost daily. I feel sure that my friend Miller will not consider it mean praise when I say that he has done more than any other author to show bee-keepers how to avoid the thousand and one pesky little plagues with which they are often tormented. Even if he had not shown us how to receive any more surplus honey, his book is abundantly worth its price, for the simple reason that it shows us how to reduce the friction to the minimum. I wish space would permit me to go on and notice all the nice little hints that are given. For instance, I have given bees access to combs of honey or partly filled sections, and how often I have wished that they wouldn't be so greedy as to tear the combs all down. Dr. Miller says: "Pile them up in supers out of doors, covering them up and leaving a hole large enough for only one or two bees to pass at a time." Why, to be sure! how simple! and yet I had never thought of it. I have tried it this spring, and it works well. Another thing: He leaves his cellar-doors open the night before the bees are to be taken out, and in the morning they are quiet, and do not *rush* from the hives when taken out. He also tells how to take sections from wide frames and supers, how to put fdn. in the sections, about dress for the hottest weather, double hives for full colonies, etc. There are also many handy little implements described, that help to make matters move easily. As the months rolled by, and one stage succeeded another in the "year among the bees," I found myself watching eagerly to see how the next step would be taken. I had been upon the same ground, and it was interesting to see *how* my friend Miller would *step*. And then the charming manner in which the book is written! Let me give an extract or two: "Now that the apiary is in running order, you may want to take a look at it. 'You don't think it looks remarkably neat?' Neither do I. If I had only six dozen colonies, and were keeping them only for the pleasure of it, I should have their hives painted, perhaps ornamented with scrollwork; but please remember that I am keeping them for profit, and I can not afford any thing for looks. Some of them are painted with a cheap reddish-brown mineral paint; but that was years ago, and they look very dingy. More of them are unpainted, and the oldest of these look dingier still. I suppose they would last longer if painted, but hardly enough longer to pay for they paint. Besides, in the many changes constantly taking place, how do I know that I may not want to throw these aside and adopt a new hive? I have already changed three times, having begun in 1861 with a full-sized sugar-barrel * * *."

"Having a hive ready, now for a seat. Bro. Doolittle once tried to poke a little fun at me in convention, because I accidentally admitted that I sat down to work at bees. If I were obliged to work all the season without a seat, I am afraid I should have to give up the business from exhaustion. Moreover, if I had the strength of a Samson I don't think I should waste it stooping over hives, so long as I could get a seat. I generally have three or four seats about the apiary, and I just take for a seat a box in which 500 sections have been shipped, whittling a hole in it to carry it by. By placing it differently, it gives me a seat of three different heights, suitable for working at a one-story hive, or one with supers tiered up on it."

I can not close without saying how agreeably I was surprised to find that friend Miller contracts the brood-nest to *four or five combs* at the time of putting on the supers; also that his bees usually require feeding in the fall, and that he feeds them sugar syrup.

Brother bee-keepers, you will learn many little "kinks," and enjoy a real treat, if you read "A Year Among the Bees." W. Z. HUTCHINSON.

Rogersville, Mich.

DR. GALLUP AND J. P. ISRAEL AT HOME.

THE ADVISABILITY OF GOING TO CALIFORNIA TO MAKE MONEY AT BEES.

I HEREWITH present your readers with a few "notes by the way," on a trip to California. We left Kansas City, Mo., Friday, Nov. 27, on the emigrant car of the A., T. and Santa Fe R. R.; fare $45.00. Right here let me say that the emigrant car is hitched to the express train, and makes the same time as first class. My wife did not like the idea of traveling that way, but now she says she prefers to go on the emigrant car, rather than to take first-class passage at the same price. We arrived at Emporia, Kansas, where was a fine stone depot, two stories, and a town of 12,000 inhabitants. On the morning of the second day we arrived at La Junta, Col. We passed through the great plains of South-western Kansas during the night. About 11 A. M. we are only 34 miles from the Spanish Peaks, where all is white with snow. At Trinidad, Col., many of the houses are made of adobe, or dried mud, flat roofs; 6000 ft. above sea-level. At 1 P. M., going up the mountains, grade 113 ft. to the mile; takes two engines to pull us. We pass through a tunnel, and enter New Mexico, 7622 ft. above the sea. Here it is quite cool, and here, also, we saw some mountain goats. The scenery is very rough—large rocks and vast lava-beds. We are now 1000 miles west of Kansas City, and have passed hundreds of miles of treeless plains, without enough grass to feed a prairie-fire.

The fourth day we crossed the Colorado River into California, and traveled all day with nothing but sand and cactus in sight. I thought if all of California were like this, that I would leave very soon. On the fifth day we passed through a tunnel 1¼ miles long. I then saw some good country within 30 miles of Los Angeles, at which place we arrived in the afternoon. We rented a house and got to housekeeping, and I bought myself a pony and took a ten-days' ride over Southern California. I started Dec. 7th, and on the first night stopped with Dr. Gallup, of Santa Anna. It seems that the doctor has no family—at least not here. He has a nice young orchard and vineyard, and had a very nice house just ready to plaster. The doctor has not kept any bees for several years. He says the bees went back on him, and that they will chew a raisin right up after it is dry. His statement about making a start with $50 or less, applies to himself, not to any one who has no trade. He is a water-doctor, and works at his profession, which is a good one for this country, as so many come here sick.

The second day on horseback I traveled 47 miles, and went 22 miles without coming to a house. I then would have fared poorly if I had not had my blankets to sleep under. I next saw the grand old ocean for the first time. The breakers, when seen from a distance, look like a long line of clothes flapping in the wind.

The third day I came to the ranch of J. P. Israel, and found it after dark. I almost got lost in the cañon, which is a hard place for a stranger to find, twelve miles from a small postoffice and store, and about 35 miles to San Diego; he seems to have a first-rate location, with only one apiary anywhere near him. I found he was and had been "ranching" it for three years. Mr. Israel is an old man, about 50 years, I should judge. You remember the laugh he had on the Heddon bee in his big report. Well, I should say his bees were very much like the Heddon stock, for I did not see a hive that had all the bees with even one yellow band. I called them very poor hybrids.

Dec. 10th, the day I was there, the bees were working on some weed that grows on the mountains, and some of them had good loads of honey, which made them drop. There was not a day during my ten-days' trip (from the 7th to the 17th of Dec.) that bees did not get honey. Think of that, O ye "friz-up" bee-men. Mr. Israel uses dry horse-dung for smoke, and it works first rate. The way the bee-keepers of Southern California work their surplus boxes is like this: Suppose you have a Simplicity hive with a solid honey-board, small enough so that the bees can come up around the outside edges. Put on your upper story, then fill it with Harbison boxes, the ends of the boxes being open. The bees have to go in at the end. They then can't work from one set to the other from the bottom, but have to come around to the end. The ends of each clamp come within ⅜ inch of the side of the upper story.

To sum up the whole matter: As regards myself I am a young bee-man who could and did make a good living from bees, from one year to the other, in Missouri. I came with my family to California with the intention of keeping bees, and staying one year anyhow. I did not come to "bach it for two or three years. After riding over 300 miles I have settled in Los Angeles, and gone into some other business. I have not seen a bee-man who says he can make a living from bees. Since I have been here I have seen 196 cans of extracted honey, of light color, as light as white clover, all candied, and one year old, sold at auction for $1.55 per can of 60 lbs. However, we like this country and expect to stay, but don't advise any one, who can make a living where he is, to come here unless he has lots of money; and if he wants to keep bees, he must be willing to live in the most out-of-the-way place. Any person who can't make a living in the States had better stay away from here. There are more persons here who can't get work, than anywhere else.

Los Angeles, Cal. F. J. FARR.

Thanks, friend Farr, for your very fair and impartial statement in regard to the climate and facilities of California.

HOW TO SELL OUR ENTIRE YIELD OF HONEY AT GOOD PRICES.

FRIEND MARTIN'S INSPIRATION.

IT is now 2 o'clock at night. The above grand idea struck me so suddenly that here I am at my desk to give you the benefit of my thoughts; and without further remarks I will proceed to the great subject.

A certain class of writers for our bee-journals continue to reiterate, from time to time, their belief that there is an overproduction of honey. I shall adhere to the belief that there is not an overproduction, and that, should our yield be the greatest ever known, it could all be sold at remunerative prices. The first proposition I shall lay down is, that we have a great country, and there are thousands of localities where no bees are kept and no honey produced, and where honey, if sold, is ordered from distant points, and at high rates. We frequently receive letters from friends from various parts of the country, ordering a small amount of honey, telling us they can not purchase honey without paying exorbitant prices, and then not knowing if it is pure honey. Now, my friends, why should this condition of things be? Let me answer the question. It is for the reason that we are educating a class of producers, and not one is educated to sell the product. Friends Heddon and Jones and others, have around them each season a number of students. We hear of their progress, and graduation as experts, to secure tons of honey; but there their education stops; and unless they have the natural tact as salesmen, their honey is shipped to perhaps an already overloaded market. Now, what we want at this stage of apicultural progress is educated salesmen. Let them first learn all the details of management of bees and production, then let them study the various methods of selling honey, supplying a wide constituency, and we should predict that their profits would be far more than if they were merely producers. If we had a few honest and energetic salesmen in every State there would not be a complaint about overproduction.

But I think much can be done without such salesmen, by co-operation. For instance, Bro. Russell, on page 347, shows us that he has the tact of a salesman. He says he wishes that village of 10,000 population were near him. Now, Bro. R., hunt up such a village. Isn't there one in your county? Then you could order of us who don't know how to sell to advantage. You know W. Z. Hutchinson says it puzzles him to hear a man tell how easy it is for him to sell his honey, but he never wants any more to sell again. It is easy to sell a small crop of honey, or even a tolerably large crop, if you have a monopoly of the business; but, ten chances to one, other bee-keepers enter the market in competition with you. Now, where such competition takes place, instead of letting their interests come in conflict, let them, in a brotherly manner, try to spread their product over a greater surface. That is the whole question in a nut-shell. We dump our product down here and there in lumps, when it should be evenly distributed. This can be done only through co-operation and educated, energetic salesmen. Shall we have these? It rests with bee-keepers themselves to answer these important questions. J. H. MARTIN.

Hartford, New York, May 22, 1886.

Friend M., I guess we'll have to start a school to teach people how to sell goods. Now, I am not sure that any school would be better than the one that lies before every producer —the school that we all have to learn in from stern necessity, and perhaps by sad lessons of experience. But it is true, that the honey-product is by no means evenly distributed. In the immediate vicinity of some enterprising bee-keeper, honey is often retailed as low as 10 cts. per lb. for extracted, and from 12 to 15 cts. for comb honey; whereas there may be a hundred localities, and perhaps not many miles away, where the old prices of from 20 to 30 cts. a pound are ruling. If some system could be inaugurated whereby the whole country could be thoroughly canvassed it certainly would be a wonderful help to our industry.

HONEY-JUMBLES.

Within an hour we have opened a barrel of jumbles, made by one of the largest baking establishments in our State. The manufacturers guarantee them to be made from pure honey—not a particle of sugar nor molasses about them. The advantage gained is, that these cakes never dry up. You may buy a barrel full, and they will be just as nice for the children to eat after a whole year as if they were just made by mamma. We have for the first time put them on our wagon that goes over town every other day. The retail price is 15 cts. per lb.; wholesale, 8 lbs. for a dollar. If these honey-cakes were extensively introduced, this trade alone would consume immense quantities.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from May 15.

CHAPTER XVII.

Whatsoever thy hand findeth to do, do it with thy might.—ECCL. 9: 10.

Before taking up the matter of sowing seeds, I wish to digress a little and touch upon a subject which particularly belongs to the last half of the title of our book; namely, how to be happy while doing your work.

It was between four and five o'clock in the morning, in the month of May, when an acquaintance called. There had been so many applications for work that I had put a notice in one of our county papers, saying that I could not promise employment any more. This acquaintance evidently had something on his mind; but pretty soon he came out with it, and spoke somewhat as follows:

"Mr. Root, I don't want to trouble you by asking you to take any more hands into your employ; but I have a young half-brother living with me whom I am rather obliged to support, and he has nothing at all to do. Now, if you can set him at work anywhere, and at any kind of wages, no matter what, I shall be greatly obliged to you. He is to have his board any way, so it will be thankfully received, no matter what you pay him, even if it does not half pay for his board. You can try him, if you wish; and if he does not please you, don't keep him; but I would much rather he would be at work than to be lying around idle."

"How old is the boy, friend S.?"

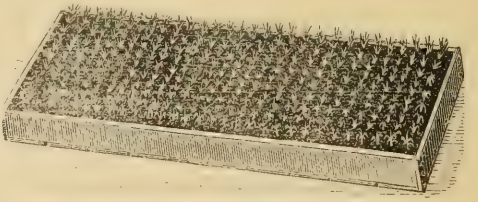
"Why, Mr. Root, he is only fifteen years old; but I believe he is a good boy, and intends to do right. Can't I send him to you on trial?"

The result came with an anxiety and look in his manner that touched me, and he went away without my ever thinking to ask the boy's name. Pretty soon the boy came — a sober-looking little fellow with what seemed to me a rather sad air or sorrowful countenance. I asked him if he was the boy who had come to work on trial. He said he was. I asked his name; and when he gave it it startled me. It was a plain, common name, and nothing singular about it, only it happened to be, both surname and given name, exactly the same as that of my wife's father. My mind ran back to the time when I first met my wife. When I inquired who she was, somebody told me that it was Susan Hall. After a little I learned that her father's name was Daniel Hall. An honest, earnest, hard-working old gentleman I found Daniel Hall to be, and it was he who gave me my first impetus, almost, in this busy world; for when the subject came up, he frankly objected to my poor self as a suitor for his daughter, on the ground that I had no stability of character. I was in the chicken business somewhat, then crazy about electricity, etc., and shifting about; and, worst of all, I was not earning any thing, nor even fitting myself for any special branch of usefulness. Good old Daniel Hall's words stirred me, and I declared I was going to commence forthwith to be good for something. It did not take a very long time nor much hard work on my part to win the confidence and respect of my wife's father; and I won it, too, long before we were married. In due time he began to lean upon me, as it were; and when I became a Christian he was willing to trust me for all time to come. On his dying bed he begged me to take charge of his property, and see that his wishes were all carried out in regard to it. He talked with me freely and frankly in regard to the great unknown beyond the tomb.

Well, when I asked the boy his name do you wonder that I was startled when he said it was *Daniel Hall?* Perhaps the memories awakened by that name made me take a deeper interest in him, and study him more fully. I took him down to the creek-bottom ground where the men had been digging out the stumps and plowing out roots. I had been trying to get the small boys interested in picking up the roots and stones so as to make the ground clean. Like most boys they could see only back-aching drudgery in the work, and they not only made slow progress, but they did not *see* half of the stones that were so plainly visible to *my* eyes when I came around. I explained to Daniel what was wanted. I took up a basket and picked up roots with him for a while, as I generally do, that I may be sure the boys understand just what is wanted. Well, I was greatly surprised to see Daniel take hold and take up the roots rapidly—yes, as fast as I could—even saved steps and saved motions by calculating with his mind while he made his hands fly rapidly. I had seen boys start a good deal that way before;

and, please don't blame me when I say that I feared it would not last over an hour or two; but it did. He worked all the forenoon and all the afternoon; and when we gave him other work for a change, he worked hard at that. The boy had been out of work until he was *hungry* for something to do. Oh, how I do *like* to find people who are hungry for something to do, and who are accordingly thankful when work is furnished them, no matter what kind of work it is! I told my wife that my heart was turning strongly toward her father's namesake.

Some time after this a lady called, begging me to try *her* boy; and as business was then crowding I consented to try him also. He was about Daniel's age; and with Daniel for an example, the boys soon came to be a kind of "span," as it were. Of course, they would have their fun when they were at work together; but altogether I felt happy about my two new boys that were at work outdoors out in the garden. A great part of their work was setting out little plants from the seed-boxes, and, like most other boys, they pretty soon began to get tired of it; but I told them it was the only work I had for them to do, and that they would have to work as long as they could, and when they got tired they could mark off their time and rest. They each get 7½ cts. per hour. This, you know, would only about pay for their board; and as many hands in the factory work over-hours during the busy season, as it is now, the first I knew, my two boys, Daniel and Walter, were working till seven o'clock without their supper. I expostulated a little; but Walter said they had hard work to pay for their board unless they put in more time than ten hours a day; and he said they did not mind waiting until seven before they had their supper. I told them I didn't believe they could work from one o'clock till seven, neither in justice to themselves nor to myself; and I found by watching them that they frequently got so tired during the afternoon that their work did not amount to very much; but toward night they would frequently brighten up and set out plants at a pretty good rate. To show you what kind of work they had, I will give you a picture right here that I have used before.



A BOX OF WHITE-PLUME CELERY-PLANTS AS IT APPEARS WHEN FIRST TRANSPLANTED.

The little plants were taken out of the seed-boxes and planted in the open ground, in just the order they are seen above, using the transplanting-frame, shown on page 136, to space them. Now, in transplanting cabbage plants we put one in the center of each mesh; but with celery we put two in each mesh—one in each of the acute angles of the six-sided opening. I knew the boys were not making the progress they ought to make, and yet I knew, also, that they tried hard to be industrious. Each one had a large wide board to rest on while he worked at his plants. The wide board, you will notice, prevented him from injuring the smooth surface of the bed or the plants, where the plants had been transplanted. The wide board is laid right across the frame, so they can get close down to their work. It also allows them to recline, if they choose, resting part of the time on one side and part of the time on the other side. The ground is kept constantly wet by means of a sprinkler. Well, I told the boys to look at their Waterbury watches and see how long it took them to transplant a frameful. It took them about four hours apiece, while Mr. Weed, who has charge of the greenhouse, could plant a frameful in about an hour. The trouble was, the boys had got tired and wearied of their work; and even if they tried they could not awaken an interest in it, and did not enjoy it very much, simply because it had become monotonous.

Now, please don't be impatient, dear reader, because I dwell so long on these little details in regard to a couple of ordinary boys setting out plants in a garden. The boys were just about such boys as I used to be; in fact, I saw myself as I watched them, Now, I did not keep an eye on them solely because I expected or wanted to *make some money* out of my celery-plants; but I kept a careful eye on them because I was working and praying over this great problem,—

"WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT."

What should be done to give these boys an *interest* in their work? What should I do to enable Daniel to set out plants, with the same life and energy that he picked up roots and stones the first day he worked for me? Well, I had a plan in my mind, dear readers, and I was just getting ready to put it into practice. It is a plan that works wonders, if wisely and judiciously used. It is the plan that makes the busy workers in our factory, in a great many departments, enter with their whole souls, as well as with their whole strength and muscles, into their work. Go into the folding-room and see the girls make the sheets of paper fly when it comes paper-day; go watch them in the room adjoining, where they are wiring frames to hold the foundation; take a look into the smoker-room; yes, in the printing-office. How is it they become so expert and rapid that your eye can hardly follow the motions of their hands? Why, it is just on the plan I had proposed with the boys. I went down one morning and spoke to them something as follows:

"Boys, I will tell you how you can make more money than you are making now, both for yourselves and myself. I will give you five cents a hundred for setting out celery-plants, providing you do it so well that they will grow every time. If they die, you must set out more in their places, on your own time. Now, five cents a hundred will make just about the wages you have been making; but I rather think that, if you are working by the piece, you will get along a good deal faster."

One of them replied that he did not think they could work a bit faster than they had been doing, for they had stuck to it just as busily as they possibly could. I told them they could try it, and that, if they didn't do any better, they could have their regular wages by the hour, but that I rather expected they would improve some. Can you guess how it turned out? Why, when I came around that way, an hour later, the boys were just bending over their plants, and making their hands fly as if life and death depended on it. Their frames were filling up as if by magic, and their faces were full of animation and excitement. Daniel looked up honestly, and said something as follows:

"Why, Mr. Root, we are going to make a pile of money if you let us work this way."

"Well, I am glad of it. If *you* make a pile of money I think I shall too, for we are likely to need all the nice celery-plants we can possibly raise."

They did not feel like working till seven o'clock that evening; but as they had made nearly double their usual wages (one a little more than double, and the other, I believe, a little less), they felt as if they could stop at the usual stopping-time, and then take a playspell. During the afternoon one of them ventured the remark, "Mr. Root, if we work by the piece can we stop and look at things, and walk around and stretch ourselves when we are tired?"

I told them that, when they were working by the piece, they were their own bosses. They could work or not, just as they chose, providing the work was got along at a reasonable rate. Now, friends, do you see the difference in working without any particular interest in your work, only to have the hours go along and night come, or in being a partner, as it were, in regard to the results accomplished? These boys *enjoyed* working under the high-pressure principle, in a way they could not possibly enjoy working by the hour, especially when the work was something that had become monotonous and tiresome. One great truth brought out here is, that it is not so much the kind of work we are doing, but the way we look at it, and the motives that prompt us. Why not let everybody work in this way? Well, in the first place it is not possible to arrange all kinds of work so it can be done by the piece. Again, there is a constant disposition to slight the work unless there be some test or condition. In the above it was clearly understood that the plants must be put in the ground so that they would live, and the boys must watch them and water them until they had become rooted. Another thing, we can not well set people at work by the piece unless they are honest and conscientious. Where a workman has a disposition to cheat or to be tricky, the employer will get beaten, sooner or later, unless his eye is *constantly* upon him. With children or younger people, there is a constant danger of misunderstandings and difficulties. Even our good friend Walter complained the first day that his foreman, Mr. Weed, didn't give him full credit for the full number he set out. Now, before we start out in any such kind of work, our details and system should be made so as to avoid mistakes as far as possible. As an illustration: The transplanting-frames we use do not hold even numbers of plants. When they were made we did not think about piece work; but we are going to work to-day to have some frames made that hold an even number, 500 cabbage-plants, or 1000 celery-plants.* In that case the boys will avoid every chance of making a mistake. All they have to do is to count the number of frames full set out, at 25 cts.

---

*A frame made 3×4 feet 4 inches *inside*, will just about do it.

a frame for cabbages, or 50 cts. a frame for celery. Before you adopt these figures it may be well to tell you that we have decided —that is, the greenhouse manager and myself—that 3 cts. a hundred is about a fair price to pay the boys and girls for transplanting.

Well, how shall one get this extra vim and interest in his work, who is working for himself, and is not hired by the piece or hour? My friend, how does your wife get that extra vim and energy with which she works on wash-days, or in the morning to get breakfast on time? when there are two or three little chicks in the household to be dressed and fed and kissed and got to sleep, how does she do it all, and make all of her other duties come to time? Well, I think you can tell best by taking a look at her. Watch and see how she economizes, by doing something with one hand while she does something else with the other hand. See her rock the baby with her foot, while her hands fairly fly among the culinary implements, singing with her voice meanwhile, perhaps, to hush the baby. Does *she* enjoy her work too? Why, I think she does, especially if her heart is full of love and praise to the Master. One great element in her happiness is the consciousness of having a husband who is using *his* brain and muscle in the same way to make every thing count for her and these same little ones. Dear reader, are *you* that husband? Perhaps you say you don't like to be crowded all the while on high-pressure principles. Well, may be you think you don't; but my opinion is, that more happiness is found among the real busy people than among those who have not very much to do.

My good father once took a notion into his head that he was getting to be too old to work on a farm. He moved into town and stayed there two years in order to take things easy, and enjoy life. So far as he was concerned, it was a tremendous failure. He worried and fretted, and became more unhappy than he ever was before in his life, and got back to his usual piece of mind only by going back to the old farm and staying there all the rest of his days. Work while you work, and play while you play. I do not know of any better preventive for getting sick than to be so full of business that you have not time to be sick. Suppose you are conscious of a lack of interest in your work. Suppose you have got to feeling that it is a kind of drudgery, and that you hate the sight of it. What shall you do? Well, in the first place, apply your mind to it and busy your brain in plans for shortening and improving and excelling in your allotted task that seems like drudgery, and then get right down to it and push; that is, work as if your life depended on it, even if there does not seem to be any great reason for pushing things along. If you try hard you can see the dimes ahead of you, just as the boys did; and if you put in with that kind of energy and enthusiasm, the dimes will surely come. I have had hands in my employ who did not seem to be conscious they were in any way at fault, when they wouldn't earn over two or three cents an hour, at a fair valuation, on the amount of work they were accomplishing. When spoken to about it they felt hurt, and insisted they were doing good fair day's work. Oftentimes nothing would convince them of the error of their ways; or, to put it more plainly, nothing would convince them that the dawdling manner in which they were working was only next door to stealing, until they were started on piece work. Let some good hand sit down beside them and show them how much could be accomplished in an hour, then tell them they must give up their places or work by the piece, and in a little time they will be astonished to find it an easy matter for them to do as much in one hour as they have heretofore done in *four hours.* Now, this state of affairs is not so very uncommon. There are carpenters and farm laborers and mechanics of different kinds around, hunting for jobs, who, when set at work, do not accomplish as much in four days as good workmen will do in one day. It has always been a puzzle to me to know how manufacturers, knowing these things, could pay men one uniform price for a day's work; and how about reconciling these things with the demands of the strikers? Now, then, if you want to have something to do, you must be alive and awake; and if you want to be happy in doing that which you find to do, you must alse be *alive* and *awake.*

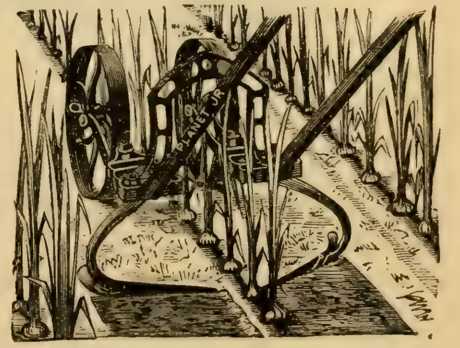
Eight hours has been talked about as a day's work a good deal of late; and, in fact, I believe eight hours has been made a day's work by the laws of the State of Ohio; that is, if you employ a man at so much a day, and neither he nor you mention the number of hours he has to work, he can collect his pay by working eight hours only. I am ready to grant that eight hours of live earnest work is worth fully as much as ten hours of work where there is no life or interest in it; but it seems the demands of the present age point strongly toward making the amount accomplished a gauge of a day's work, and not the number of hours put in. It is an easy matter to get in the hours; and where one who is working thinks principally of getting the hours in, without regard to the amount accomplished, he will very soon be out of a job, or be working for small pay. Money is an excellent stimulant to be used in getting people to move and think lively; but woe betide the one whose only and highest ambition is to *get money;* that is, to get it without any particular regard to the equivalent he gives the world in exchange. Is it not a thousand times better to be working for *Christ's* sake instead of for *money's* sake?

CHAPTER XV.

SOWING THE SEED.

The hand of the diligent shall bear rule; but the slothful shall be under tribute.—PROV. 12: 24.

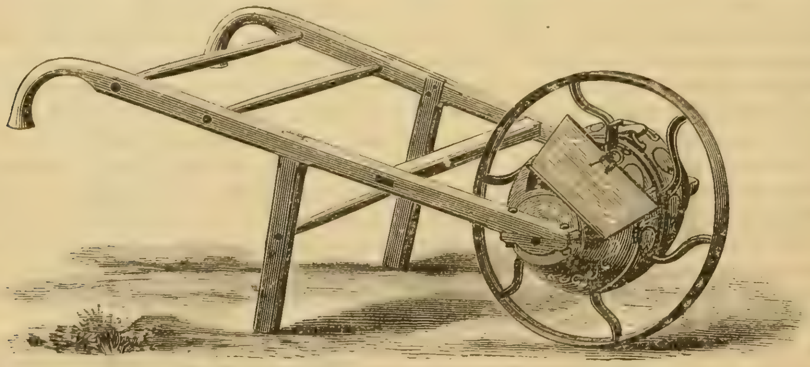
At the close of Chapter XVI. we had our ground prepared, ready for sowing seeds, or for setting out plants. Well, after we decide what is to go on the ground, it is to be marked, for we want our plants or vegetables in rows at exact distances apart, and the rows perfectly straight, or as nearly so as we can well get them. There are many kinds of markers used for laying out the rows, but I am free to confess that I am not satisfied with any thing I ever saw or heard of. You can get along very rapidly in marking your ground by having a marker with teeth set as far apart as you want the marks. I object to every thing of this sort, because it is easily bumped from one side to the other. A good many farmers use a corn-marker with a sort of shoe, or sled-runner, in place of the teeth, and this is, I think, a great improvement; but I have yet to see one where these runners were easily shifted from one distance to another. A furrower and marker is advertised and illustrated in many of our agricultural papers, having a revolving steel wheel to go after the steel runner, that carries the machine steady; but this machine has the fault I have just mentioned, of being tedious to adjust for rows at different distances apart. If you sow your seeds with the drill, the drill itself has usually an arrangement for making a mark for the next row; but I don't like this arrangement, because it is not sufficiently accurate. We want our plants so perfectly in a line that the latest improved cultivators can be made to run within half an inch of the plants. Now, this will be impossible if the plants stand zigzag — one out of row on one side, and one out of row on the other side. Stretching a line does very well for setting out some kinds of plants; but it is too slow and too much machinery — the line must be shifted every little while, and measurements must be made at each end, and even then the rows will be getting wider at one end than at the other, every little while. Something to be drawn by a horse, or a span of horses, that will make two or more marks at once, is what is wanted; and the machine should be capable of adjustment, so as to make these marks of any depth or any width. For planting out small celery-plants, a V-shaped groove, perhaps not more than an inch deep, is all that is wanted, while for planting potatoes we want a furrow as deep as would be made by a one-horse plow. The machine should be capable of doing either, and making marks or furrows of all depths and widths between these. Darnell's furrower and marker comes closest to all these requirements, but it needs improving considerably before it is just what is wanted. Lest you be inclined to think it is a matter of small moment in regard to dropping seeds



IMPORTANCE OF HAVING YOUR GROUND IN STRAIGHT ROWS, ILLUSTRATED.

or setting out plants in a straight line, I want to give you some illustrations. The figure on the foregoing page comes from the catalogue of the "Planet Jr." garden-tools.

The wheel-hoe is arranged with a pair of knives that go close up to the plants, as you will notice. These knives are ground sharp on a grindstone, so they will go through the soil easily, and cut up every thing before them. Well, if your plants are in a line you can set them so close together that the soil will break up fine from one knife to another, so that, after having run through it, the cultivation is finished. If you had them in irregular lines, one plant one side of the line and one plant the other side, you would be under the necessity of doing a lot of hand-work to get your rows clear from weeds. If you have ever weeded rows of onions or parsnips, you can form some idea of how expensive it is. Before sowing your seeds or setting out your plants, it is an excellent idea to strew ashes along in the furrow; or, if you choose, put in guano, properly prepared poultry manure, phosphate, bone dust, lime, plaster, or any other of these substances used as fertilizers. All have their office for different crops or different soils. The handiest thing we have ever used for this purpose is a machine from the "Planet Jr." folks. We give a cut of it below.



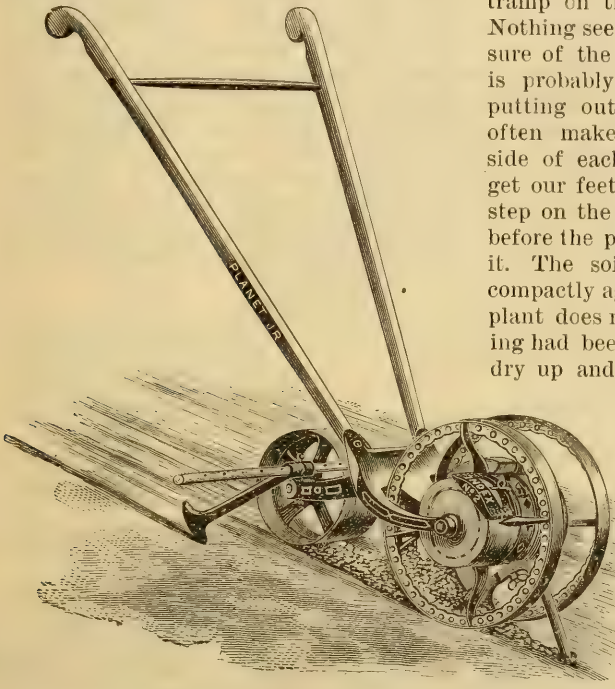
THE "PLANET JR." SEED AND FERTILIZER DRILL.

The machine holds half a bushel. It is filled up at a little door shown in front. It has a hollow drum, or barrel; and if you want to sow bone dust and phosphate mixed together, the machine is the best mixer, perhaps, ever invented. It is easily adjusted, so as to make your fertilizer go in fast or slow, as you choose; and it dusts it, too, among the soil at the bottom of the furrow to perfection. The same implement drops peas, beans, and corn to perfection, although it does not cover them up. I know there are other machines made that sow the seed, put in the fertilizer, and cover it up, at one operation; but it will seldom pay to use such an implement for market gardening, where we seldom sow more than a single acre to any one crop. A boy from twelve to fifteen years old will run the fertilizer-drill, and consider it fun. I should consider it well worth all it costs, for distributing ashes alone. If dry peat is sprinkled under the roosts of your fowls, and the whole raked over occasionally until it gets perfectly dry, this machine will sow it in the drills beautifully. For sowing smaller seeds, such as celery, turnip, cabbage, onion, sage, carrot, spinach, salsify, parsnip, beet, and sometimes beans and peas, a machine is illustrated on the following page.

This machine is much like the other, only it is smaller. It has a roller for rolling the seeds after they are sown. It has also a marker. If the seeds are dropped in furrows of the right depth, and the soil is nice and properly prepared, we usually do the covering with the smoothing-harrow. If the ground is dry, I would then go over it all with a heavy roller.

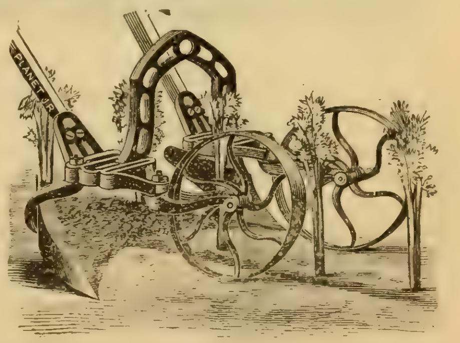
Of course, it is not *necessary* to have any of these drills for sowing seeds, although it was a great convenience and a saving of time. Some market gardeners decline to use seed-drills of any sort, saying they can not afford to take the chances of having ground, so expensively prepared, improperly seeded. They mark out their ground as mentioned above, then the seeds are put in by hand, the owner preferring to see with his own eyes that every foot of ground has the proper amount of seeds.

The next thing is to cover the seeds. Perhaps you think this is a very simple matter, and that nothing further is necessary than to get some dirt over them in whatever way comes handiest. Well, under some circumstances throwing dirt over the seeds will do



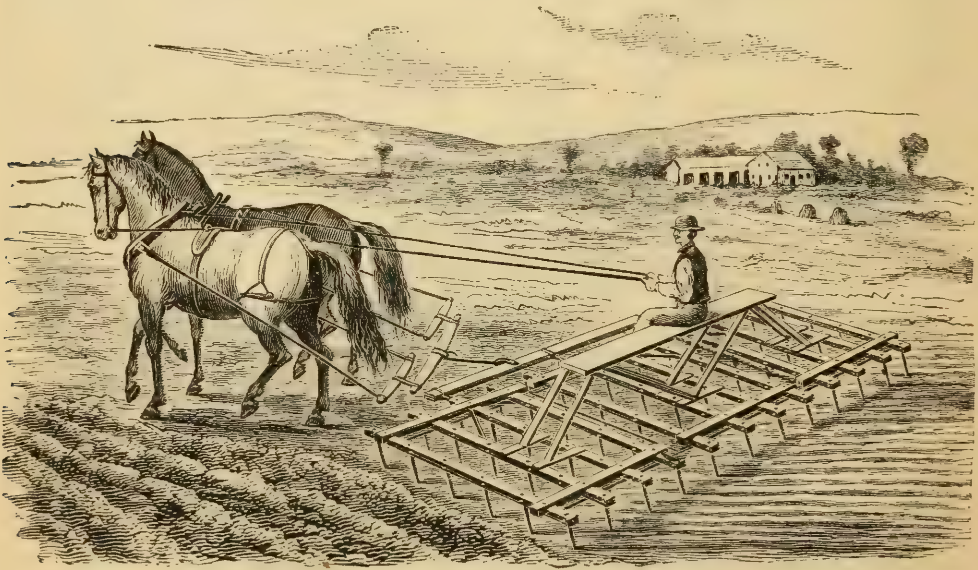
“PLANET JR.” SEED-DRILL, NO. 2.

very well, and then again it won’t answer very well. If the weather is dry and the ground hard, and your seeds are simply covered with loose dirt, if it should not happen to rain they may lie a month without germinating. What is to be done in such a case? If it does not rain you can not make it rain, and watering the whole field to make the seeds germinate would be out of the question. Is there any thing else to be done? Yes, there is something else. After covering the seeds with loose dry earth, step your whole weight on them, and the earth will be so closely pressed to the seeds as to furnish the requisite moisture to cause them to germinate, when they would not do so otherwise. After we had learned the art of making celery-seeds germinate quickly and surely in the greenhouse, as we thought to perfection, we undertook to do it out in the open air; and although we followed the same plan they did not come up at all. We could not tell what the trouble was until one night a big black dog tramped across our seed-bed. In the morning I felt like banishing dogs, both big and little, had I the power. But in a few days every dog-track was full of bright-green celery-plants, and none elsewhere. The weight of the dog had compacted the light peat that we used for covering, so as to make the seed germinate. You have, perhaps, noticed the same thing many times when some great awkward heavy man tramped over your flower-bed. Wherever he stepped, the things all grew, but they wouldn’t grow elsewhere. Peter Henderson has written a most excellent article, entitled, “Gardening with the Feet.” The idea is, that if you want seeds to germinate quickly when it does not rain, just tramp on the soil where they are planted. Nothing seems to answer so well as the pressure of the foot. A heavy roller, however, is probably pretty nearly equivalent. In putting out celery-plants in a dry time we often make them grow by stepping each side of each plant, as close to it as we can get our feet, without injuring it. Next we step on the plant so as to let one foot come before the plant and the other foot behind it. The soil is pressed up so solidly and compactly against the little roots that the plant does not wilt; whereas if the tramping had been omitted the plants would all dry up and die. Remember, however, that this tramping or compacting the soil is needed only when the ground is dry. If you set out plants, or plant seeds, just before or just after a rain, don’t tramp them; in fact, it would have the opposite effect, for it would make the soil bake into so hard a crust that the plant could never get through it. The easiest way of getting the fine dirt over the seeds, unless one has a machine to be drawn by horses on purpose, is the Planet wheel-hoe, arranged as shown below.



THE “PLANET JR.” DOUBLE-WHEEL HOE EARTHING UP.

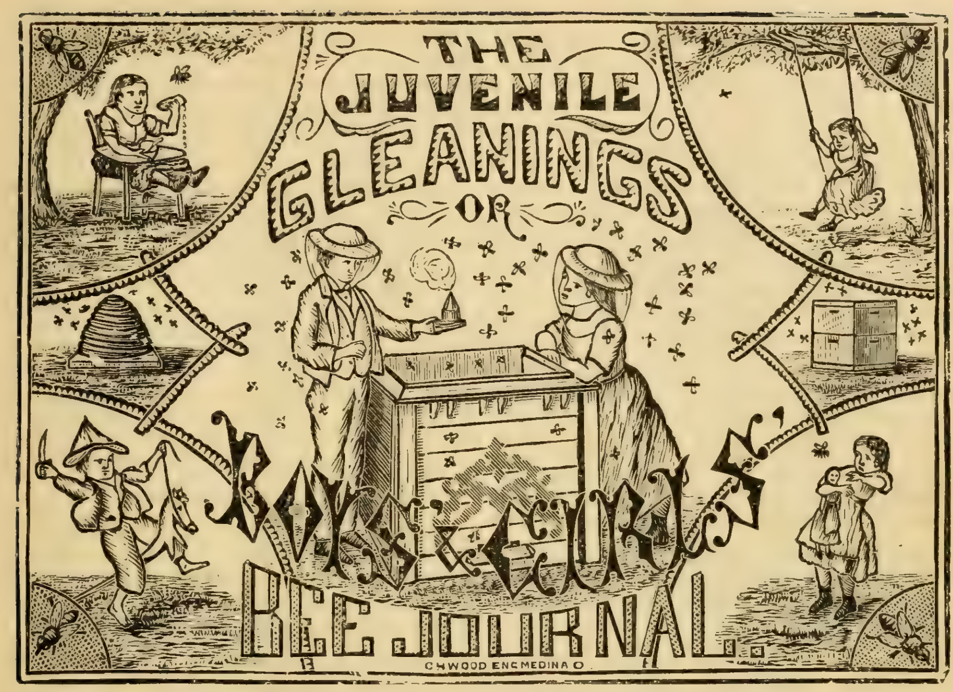
In the above illustration the machine is shown rigged for earthing up celery; but the same arrangement, with the shovels set a little closer together, covers up seeds beautifully, and a boy will do it as fast as he can walk. If the ground is dry he can go slow enough to tramp the seeds at the same time. If a heavy rain comes after the seeds are planted, before they are up, it is sometimes quite a saving of time to go over the ground and break the crust—killing the little weeds before they have come up, and this is by far the simplest, easiest, and most effectual way of killing weeds of any kind. Raking the face of the ground with a fine-tooth rake does the work beautifully. On a larger scale, the Thomas smoothing-harrow does it to perfection, and I wouldn't think of trying to raise corn or potatoes without running this smoothing-harrow over them just before or just after they burst through the surface of the soil. This smoothing-harrow is such a splendid tool that I think I will give you a picture of it here.



THE THOMAS HARROW AS USED FOR CULTIVATING POTATOES.

Terry says a field of potatoes of the proper shape can be harrowed six times over for 90 cts. an acre, and it is pleasant, easy work for man and beast, in contrast with the above plan of cultivating it in the common way, and the smoothing harrow does it ever so much nicer, because it moves every foot of the ground. The potatoes and corn are as effectually cleaned as if you took your fingers and removed the dirt from around each stalk and fined it up and put it back again, as you do when weeding onions by hand. I once harrowed a piece of corn after it was four inches high, and the only horse I had was a colt only half broken. As she was quite young, I used only one section of the harrow. After I got through my cornfield it looked as if it were ruined. The corn that had stood so beautifully in the morning was knocked over and tumbled every way, some of it even broken off. It was my first experience in harrowing corn so large, and I went home that night sick of the Thomas smoothing-harrow, sick of my awkward colt, and sick of myself, because I thought I had made so bad an afternoon of it. In a few days, however, the corn picked itself up and went on growing better than ever before. As it was pretty thickly seeded, the small number of stalks that were broken off could be spared as well as not. It was the best crop of corn I have ever raised. Now, the same principle can be used in all sorts of farm and garden operations. If your ground is in proper order, you can scratch the surface enough to kill the weeds, without injuring a large class of plants, and yet every weed is killed just *before* it becomes a weed.

To be continued July 15, 1886.



He that is faithful in that which is least, is faithful also in much.—LUKE 16:10.

MYSELF AND MY NEIGHBORS.

SOMETHING ABOUT SOME VERY NEAR NEIGHBORS WITH WHOM WE ARE, NEVERTHELESS, ALMOST ENTIRELY UNACQUAINTED.

I will praise thee: for I am fearfully and wonderfully made; marvellous are thy works; and that my soul knoweth full well —PSALM 139:14.

AT length the new factory we have long talked of is under way. I would call it an addition to our present factory, but that, on account of insurance, it is to be a separate building by itself. This building is to contain all the wood-working machinery, and must be placed far enough away from our present buildings, so that, if it should take fire, it would not be likely to burn us all up. It is to be 100 x 44 feet. It is a little larger than the main building, first erected on these grounds in 1878. Now, before the work is commenced, a good deal of headwork has to be done. Mechanics and engineers, steam-engine builders, architects, and the oldest and wisest heads of the establishment, have to hold long consultations together. To avoid danger from fire, the engine and boiler are to be located quite a distance from this new wood-working factory. One of the questions that has caused much debate was, Shall we get power into the new factory by running a large shaft from the boiler and engine, or shall we locate the engine in the new building and send the power by means of a steam-pipe? We finally decided in favor of the heavy shaft. Then, again, how shall the machinery be set up? Where shall we run the railroad track that carries in carloads of lumber? How shall we unload and load up? How shall we get finished work from this new factory into the old saw-room, which is now to be used as a store and packing room? One point after another is decided slowly and laboriously; and, a good many times, after it *has* been slowly and laboriously decided upon, something else comes up that makes it advisable to change again and start on another track. After weeks and months we settle down on a plan. Our big stout team, by means of a scraper, excavates room for a basement. Carloads of great heavy stones come in for the foundation. The masons are set at work, and finally the brick come in, carload after carload. When these are in place, the carpenters put in their work, then the tinners put on the tin roof. While all this has been going on, the great machine-shops have been busy, and the new automatic engine of 100 horse-power is placed according to the plans laid down by the oldest and wisest heads in the business, and so on, until, by Christmas, we shall be able to commence making bee-hives, etc., for your use, my friends, another season. We want to be prompt next year, as we should have been this year, had it not been for the burning of our warehouse. What has this to do with neighbors, do you inquire? Well, let us see.

Yesterday morning, when I stepped out of the bath-tub, and began rubbing myself vigorously with a coarse towel, when I had got as far as one of my great toes, something fell on the floor with a loud rattle. Thinks I to myself, "What was that that dropped?" I stooped down to pick it up, and it was the whole nail of my great-toe. It was so thick and heavy and stout, that, only a few weeks before, it had taken almost all my strength to pare it off with my big pocket-knife. What should make it tumble off loose? I glanced down at my toe, but it seemed all right, and it did not seem to have lost any nail at all. On more careful inspection, however, I found that a new nail had grown under the old one. When old Dame Nature got it finished all complete, she gave notice to let the old nail slide, for it was not longer wanted. I told the circumstance to the family, and asked if any one had ever heard of a toe-nail dropping off that way. No one had heard of such a thing. My wife suggested that my toe had been bruised. I declared it had not, for I should have known it. Finally, I remembered that, a few months before, this nail had persisted so obstinately in running its corners down into the toe, that I decided I would cure it so that it would stay cured for quite a spell. I took a file from the counter store, and filed the middle of the nail until it began to show blood from the flesh beneath. Now, I knew by experience that old Dame Nature, in alarm at finding a tender spot without its natural horny covering, would draw in the covering of the nail, attempting to close up the thin place that I had almost filed through. The file cut so much faster than I expected, that I had cut pretty deep before I knew it. Some such spirit or principle seems to pervade the builders or gatherers of a bee hive. This spirit is unanimous. If a comb breaks down and falls on to the bottom-board, they seem to agree at once that the first thing to do is to take all the honey out of it and store it somewhere else. Then they fix it up, according to the best of their judgment. If you crack a comb in a frame in your manipulations, you may think that, if you put it back in the hive, the bees will mend the crack. So they will; but they first take every drop of honey from every cell along the sides of the break. Then they neatly join the broken edges until the comb is entire, and as solid as it ever was; and then, and not until then, they put back the honey. If you will look into the hive and watch them you will find the process is in many respects strikingly like the way in which nature mends a wound or a broken bone in a living animal. She clears every thing out of the way a great deal as the boys have been clearing away the lumber-piles, stones, and rubbish, preparatory to building our new factory. Then she brings in material to knit or weave together the broken tissues and the fracture in the broken bone, just as I expected the corners of the nail to draw up; in fact, the spot where I filed it down so thin soon became a little puckered, or crimped, and the nail stopped growing in from that time forward.

Now let me digress a little once more, and I shall have the foundation laid for my talk to-day about my neighbors. Did you ever notice the bees in a hive? If a young one is hatched out that is sickly or imperfect, they tumble him outdoors as so much rubbish, as much as to say, "We have no use for any thing except good, healthy, perfect bees. Cripples and deformities go by the board." An old bee that has worn himself out with hard labor is treated much in the same way. The same way with the bee that has got the nameless bee-disease, the kind that are emaciated and shining black, and that jerk and twitch. May be you have seen them. The healthy bees catch on to them and drag them out on to the grass. I do not know whether the bees hold a consultation to decide how badly a bee must be afflicted to be hoisted out or not, but there seems to be a sort of method about it. A few years ago people used to say the queen directed all these movements, but we know it is not so. The bridges across the torn and lacerated muscles, or lean meat, are united as neatly as the bees unite the broken honey-comb. Finally the surface of the wound is covered with the different layers of the cuticle, or skin. Even the lines formed by the pores on the inside of the hand all match each other in regular order, after the wound is nicely healed over. If the wound is on the head, in due time new hair grows out.

Now, dear friends, who or what is it that plans this and decides just how it shall be done? In other words, who was it, or what principle was it, in my flesh and blood that was displeased because I filed that old toe-nail so thin? It was not myself, because I knew absolutely nothing about it. Months ago these invisible forces in my body decided to reject that mutilated toe-nail and put in a brand-new one. They did not consult me nor counsel with me, for I was a very astonished individual when that great thick tough horny toe-nail that I had whittled at for so many years rattled down on the floor. Some principle that I am entirely ignorant of has been planning and working all these weeks for my best good; yes, and so solicitous is that principle, or presence, if you choose, for the well-being of my body, that not even a toe-nail was overlooked. This invisible presence, if I may so term it, or this neighbor of mine, that is living within me and for me, has been looking my bodily frame all over carefully, day by day, planning for and mending breaks and weak points. Is it not wonderful? Come to think of it, the Bible says that even the very hairs of our head are numbered. Just think of the earnest and strenuous efforts that this presence, or principle, in us all is making to keep our bodies in health. If we by mistake drink poison, it is the same principle that sets us to vomiting, and hoists out the enemy.

Years ago, one morning when I was dressing I felt a sore place on my side. As I examined it carefully to see how it came about I told my wife it actually seemed as if there were a *pocket-knife* under the skin of my body. Finally the sore spot came to a head at one end, and out stuck a piece of steel. In surprise I got hold of it and pulled it out, and it was a long sharp needle. The only explanation any one could give was, that I swallowed it years before; and this invisible and unknown neighbor of mine had been working and planning hard to get that dangerous foreign body out of my system. It had doubtless passed through the stomach and the different envelopes, the wound healing up as the needle passed through until it got out head first.

Now, then, dear reader, do you not agree with David when he says, "I am fearfully and wonderfully made"? Who is this or what is this law that has been all these ages working for the good of these physical bodies, and yet we do not know it? Truly can we say, "Marvelous are thy works." As I sat down to write this paper this morning it seemed to me more marvelous than any thing I have before witnessed in this wonderful world of ours, to think that, even inside of our fingers and toes, a teeming throng were constantly planning and working for our best physical welfare. No wonder that Paul said, "Ye are the temples of the Holy Ghost;" and that, "If our earthly house of this tabernacle were dissolved, we have a building of God, a house not made with hands, eternal in the heavens."

DO BEES HEAR TIN PANS?

WHY IS IT THAT BEES SELDOM ATTACK BABIES?

MR. ROOT:—Your article in GLEANINGS about bees hearing, makes mamma remember that, when she was a little girl, she lived next door to a lady who kept bees. This was in the suburbs of Hull, England. Every day during the spring she would hear a bell ring in the yard of the next house. She asked grandma what the lady rang the bell every morning for; and for answer, grandma brought a chair and set it near the hedge fence and lifted my mamma upon the chair and told her to look into the yard. Mamma can distinctly remember seeing a woman standing among a lot of boxes, and she had a table near her with a pan and bell upon it, and the air was full of "flies," at least so she thought (she was not 6 years old then); but grandma told her that the woman rang the bell to call the bees to their feed. Mamma was then afraid of bees. She never went into the bee yard, but grandma often did, because, when *she* was a little girl, she had lived with an aunt in France, who kept bees, and she had got accustomed to them.

A MISCHIEVOUS BABY.

I had a little brother, 13 months old, who was not afraid of bees. One day mamma went to town and left him in papa's care; and not being used to caring for babies, papa forgot him until he heard him laughing very heartily. He then went to where the sound was, and found Franky on his knees, with both hands over the entrance of the hive, and the bees were swarming over and around him; and as they would alight on his hands he would laugh very roguishly. Papa was so frightened he tried to coax Franky away, but he would only laugh, and shake his head; so papa ran quick and caught him up and ran into the house. They stung papa, but did not hurt Franky at all. Papa put up high boards all around the hives, but the little rogue would try to get to the bees every time he could get away.

The bees here in California are doing well, and, judging by other wet years, it will be an excellent honey year. One of papa's hives gave him a very large swarm last week, and the surplus box which had been left on was full of brood, with the exception of two cards. After they were cut from the frames they weighed 12 lbs. This was made from the alfalfa, and papa says it is as good as clover honey made in the east. LEWIS HILTON.

Los Alamos, Cal., April 26, 1886.

Thank you, little friend, for the article you have given us. As to whether bees hear the drumming of tin pans, see what is said in another column. I can just imagine your little brother, full of roguish chuckle, stopping up the entrance to the hive with his chubby hands. It *is* a little strange, sometimes, that bees do not attack these little innocents. When Blue Eyes and Caddie were little, although they were among the bees considerably I do not remember that they were stung more than once, and I think this was caused by the bee getting under the clothing and then afterward pinched. I think one sting is all Huber has had so far. My mother told me that she found me, when I was about a year old, poking my head clear down into a hive of bees—the first colony that A. I. Root ever owned; yet I was not stung. Why is it, do you suppose, babies are not attacked more often by bees? Well, I think it is because the child is wholly unconscious of the danger he is in, and therefore does not show any signs of nervousness. Few things will induce bees to sting quicker than the twitching of the face, or nervous motion of the hands and arms. A child never does this, because he is not afraid, and for the very *good* reason that he does not know enough to be scared. If a grown person can control his nerves the bees will treat him as kindly as they do the baby. In fact, I think with most colonies in our apiary I could stand in front of a hive and close its entrance with my hands, and the bees would make no attempt to sting; yet a person unaccustomed to bees would be almost sure to be stung. ERNEST.

BEE-KEEPING IN WYOMING TERRITORY.

WE take GLEANINGS, and are delighted with it. We can hardly understand how you can give so much for so little money. We have the first and only honey-bees in Wyoming Territory, and we were afraid they would not do well in this new country; but they gather lots of surplus honey from the wild prairie and mountain flowers, and it is very white, and fine flavored, and the bees stand the winters here as well as in the States.

I live in a beautiful valley, through which courses a large cool mountain stream in which are fish, wild fowls, and the cunning beaver; and on all sides the grand old mountains rear their peaks of snow above the clouds. I wish you were here to view the fine scenery, and enjoy the bracing, healthy air of these high solitudes. In the mountains are found nearly all kinds of large and small game, such as elk, deer, antelope, bear, mountain sheep, sage grouse, jack rabbits, badgers, wolves, mountain lions, etc.

My pa has a large collection of all kinds of minerals and curiosities of the Rocky Mountains.

JOSIE MEAD, age 12.

Ferris, Carbon Co., Wyoming, March, 1886.

HEADS OF GRAIN
FROM DIFFERENT FIELDS.

THE RESURRECTION PLANT; DOES IT COME TO LIFE IN REALITY, OR DOES IT ONLY MAKE BELIEVE SO?

I SEND you by this mail one resurrection plant. I am not acquainted with its history. I only know it comes in large quantities from Mexico, principally Yucatan. Lay the plant in a saucer of water; take it out, and it will curl up and remain so. It is said to keep for ages, apparently without life. It is said, if sore eyes are washed with the water from the saucer, that it will heal them. By allowing it to remain in the water it will put forth branches, which, when separated, will put forth roots, and make new plants. I could, if necessary, get a full history of the plant.

J. J. FITSGERRELL.

Las Vegas, N. M., May 24, 1886.

HOW SHALL I GET RID OF THE ANTS? WILL STONE BOTTOM-BOARDS ANSWER AS WELL AS THE WOODEN?

I am having some trouble this spring with the ants. They burrow around and get into the hives, and, at times, I see them with bees that are not dead; i. e., they have them pulled into their holes. Will they do any harm? I have put powdered borax around where they run, but it doesn't seem to stop them as yet. Would you let them alone till they get ready to leave?

I have just moved my bees to a new place, and put them down as directed in the A B C, but I put them on stone bottoms instead of wood. I dress the flagstone and make the entrance just like the entrance of the Simplicity alighting-board. Will bees do as well on stone bottoms as they will on wooden ones? As yet I have the common bees, but intend to try the Italian bees in the near future.

Marion, Williamson Co., Ill. W. W. GRANT.

There is only one objection to stone bottom-boards, friend G., and I am not sure that this is much of an objection; it is, that they might be cold for bees in cold weather. The fact that such bottom-boards neither warp, split, nor decay, by being placed on the ground, would be a heavy argument in their favor. It is true, they would be very cold in cold weather; but bees do not, as a rule, touch the bottom-board, I believe, in cold weather.

SALT NOT A NECESSARY ELEMENT FOR BEES.

In GLEANINGS of May 1st, 1886, I find an article headed, "More Facts to Show that Bees Need Salt," signed A. W. Osburn. He refers to another article on page 178, from W. H. Greer, entitled, "Salt a Necessary Element for Bees." He then says: "His experience relates only what is an *absolute* fact, that salt is one thing necessary in making up the food of the bees."

I have read over both articles carefully, and find no "absolute facts" given in either that show salt to be a necessary part of the food of bees. My apiary is located a few rods from the bank of a tide-water stream, fed by the Gulf of Mexico. Along its banks fresh water trickles down to meet the salt water. The bees resort to the mud, wet by this fresh water, in great numbers, but never go down to that wet by the salt water. Now here is an "absolute fact" to show that they do *not* need salt. So with the "absolute facts" to show that salt is necessary for other land animals, man included.

Many "absolute facts" might be cited to show that it is no more necessary than whisky, tobacco, coffee, or tea, none of them being food, but, on the contrary, like salt, they possess deleterious properties, and should never be used by any one desirous of enjoying good health and transmitting the same to posterity, for it is written, "The sins of the fathers shall be visited on the children." That deer visit salt-licks is no evidence that it is healthful for them, because their appetites may become vitiated by indulgence as well as that of man.

D. C. UNDERHILL.

Manatee, Florida, May 10, 1886.

Friend U., I know there are people who contend that salt is not necessary for either man or animals; but all must admit, that domestic animals are, most of them, fond of it; and as it seems to add to their comfort and enjoyment, I for one am in favor of letting them have it. Tobacco and whisky are stimulating; but I do not think it can be shown that salt has any such property. I can hardly see it as you do, that your experiment proved that bees do not need salt. May be they had obtained salt already from some other source, and did not need to go to the salt waters of the ocean; besides, the salt of the sea-water is by no means pure salt. Now, is it not possible that these same bees would take up common table salt, properly diluted, eagerly?

IS IT MUD OR SALT THAT THE BEES ARE AFTER?

On page 178, in March number, in W. H. Greer's communication in regard to salt for bees, I do not think he has demonstrated the assertion that the bees were after salt, only he is satisfied that such is the case, and probably were, as far as the meat-house is concerned, for bees like salt. In my opinion, bees work in barnyards, hog-pens, and other places where the soil is properly decayed, or in the right condition for the bees to gather material for capping their brood. I have watched them closely, and have seen them in mud holes, barnyards, hog-pens, and on old decayed wood; but I never saw them pick up a chunk of mud or a piece of rail, nor shoulder a lump of salt. I never followed them into their homes to see whether they unloaded salt, wood, or mud, but supposed that whatever they gathered from such places was material for capping or sealing their brood. I am a beginner in bee-keeping, but am interested in the little fellows. I should like to know what you think of mud balls for bee-cappings. H. A. WEDGE.

Friend, Neb.

Friend W., you have raised an interesting question. I am not aware that anybody has ever found out for sure where the bees get the material for making the cappings for brood-combs; but after what you say, I think it very likely they get it from a sort of slime that rests on the mud after the water has evaporated or sunk into the ground. I should think they would pack the material on their legs, as they do pollen and propolis; and I think some of our careful observers could trace it into the hives, and see how it is manipulated. An examination of the cappings, under the microscope, and of the substance they pick off from the muddy ground, would probably show their identity.

BEES ON SHARES; HOW SHALL THE DIVISION BE EFFECTED?

If not asking too much of you, I should like to have you explain what you say in the A B C book about bees on shares. I have taken 10 colonies of bees, and we were to take what you said in the A B C book to be the contract. Where we differ is in regard to the old stock. For example, 10 colonies in the spring, in the fall 30; how should they be divided? Please explain in detail, as all I want is what is right. I shall be satisfied with what you say. My bees have wintered very well this winter.

Lenox, Ia., April 30, 1886. J. T. HARTUP.

Friend H., it is a very difficult matter indeed to answer such questions as you propound; and about the only answer that can be given is to say it is just as you happen to agree upon. If you receive 10 colonies of your neighbor, and increase them to 30 in the fall, you would have 15 and he would have 15. A good way to divide is to let him keep one of them, then you take one, and so on. The honey and wax can be weighed out and each take an equal portion. In regard to the hive and receptacles for honey, in the absence of any agreement I would say that each one should pay for one-half of these necessaries. As you are to do the work, the cost of an A B C book or a bee-journal should be borne by yourself alone, for your partner may not care to post himself in regard to the business at all.

WHAT OUGHT A BEGINNER TO ACCOMPLISH WITH BEES?

I never handled bees in my life. I have watched others, and I have a notion that, properly handled, a man can make money by just turning his attention to bee culture. I sent to you some time ago for a Simplicity hive and GLEANINGS. I have your A B C book, and like it. I have a notion to increase my apiary of three colonies up to as many as one hand can take care of. I wish to devote my whole attention to bees and poultry.

How much ought one man to clear off from each stand of bees, clear of all expenses, each year, when working for honey alone? After I get my apiary up to 40 colonies, can I sell all the swarms as they come off? What do you think of the poultry business in connection with bees?

A SUBSCRIBER.

My friend, I do not know how we can give any advice, to amount to any thing, in the way you suggest, as so much depends upon the man; but I hope you will excuse me for saying that, as a rule, the one who asks such questions will not be very likely to succeed. Suppose I should say a man ought to make five dollars on every colony of bees he keeps. Some of our leading and most expert bee-keepers might tell me truthfully, that many seasons they have not made even one dollar per colony; or, worse still, that they have not made one copper; so you see, it depends upon the man and the season, and many other circumstances. When you get up to forty colonies, or any other number, you can sell the swarms as they come off, if you have customers, as a matter of course. Circumstances might make it quite convenient to keep both bees and poultry; but this, also, depends on circumstances. Both pursuits require that the bee-keeper be at home, and always on hand to look after them. This is so much in favor of carrying on the two pursuits together.

JUVENILE DEPARTMENT

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from $1.00 to $1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

I HAVE been very much pleased at the way you have been taking hold of the work I have suggested, especially in this matter of folding sections. You have done much better than I had any idea you could. I was wondering whether you might not raise queens. It will be quite an undertaking for little folks; but you have done so well in so many things I rather believe some of the most enterprising of you will succeed in this also. You are to get your mamma or your papa to tell you how, and then you are to do the work *all yourself*. Perhaps the A B C book, page 195, has put it so plainly that you can go to work by directions there given. At any rate, who will be first to report a laying queen of his own raising? I hardly think you could report for the next juvenile number, as it takes some little time to raise a queen. When you have succeeded I want you to tell all about how you did it. If you do well, I will promise to send you some nice little present. I can not say just now what it will be.

A good many of the little friends have been sending their letters directed to me. Although I like to receive your letters, it rather breaks up our order of business, and so will you kindly direct them to A. I. Root?

ERNEST.

A FINE PLACE FOR BEES.

My pa had 20 stands of bees in the fall; he has only 19 now. I have a hive of bees too. This country is a fine place for bees; it has plenty of poplar and linn. NORMAN A. WARD, age 13.

Onward, White Co., Tenn., May 4, 1886.

CASTOR OIL INSTEAD OF CROTON—A TIMELY CORRECTION.

Please correct the mistake in GLEANINGS, May 15, p. 415, in Tommy Brown's letter. It should read, *castor* instead of *croton* oil. It would be very dangerous to use croton instead of castor oil.

TOMMY'S MOTHER.

We are very sorry to have had such an error in our columns, especially in the juvenile department. We hope, however, that mothers will have good sense enough not to administer *croton*-oil to an innocent child, as it would result in almost instant death. Will the friends please take notice of the above?

FROM 30 TO 47, AND 5000 LBS. OF HONEY.

My pa commenced the season of 1885 with 30 stands. He took 5000 lbs. of extracted honey, and increased to 47. He has sold 4 stands, and given Aunt Em one. Pa takes GLEANINGS, and has your A B C book. He says he could not well do without them. Pa and I were looking at the bees the other day, and one stung pa on the finger, and lost its sting. I put it under a glass, on a plate, and fed it honey. It lived 41 hours and 25 minutes. I put one with it that had not lost its sting, and it was lively when the other was dead.

Jonah, Texas. EUGENE WILLIS, age 12.

TURNING THE CRANK TO AN EXTRACTOR.

Pa has 32 colonies. We have one of your extractors, and pa says it doesn't throw any honey out at the top at all. Pa takes GLEANINGS, and I read the children's letters. Pa extracts all his honey, and I help turn the extractor. We have never had any honey candy yet, no matter how cold it was. I have to walk 3 miles to school.

Mt. Erie, Ill. MATIE HEIDINGER, age 10.

Turning the crank to the extractor is another way to help papa during the honey-flow. Little folks can make themselves useful in a great variety of ways if they really think so, can't they? If you have been using an extractor for many years, friend Matie, it is certainly a very singular fact if you have had no candied honey. ERNEST.

CLIFFORD'S EXPERIENCE WITH A COLONY OF BEES.

Last June I bought 3 hives of bees. The first hive that swarmed came out four times, and the fourth time they alighted on a bush. I took a smoker and a hiver. I smoked them first, and put a hiver under them and shook the bush and then they fell into it and I spread a sheet in front and put the bees on the sheet, and after awhile they went into the hive. If they were restless I put a sheet over the hive untill they were quiet. They are Italians. When we put them in the cellar we had five, and we closed them too tight. We put over the frames two thicknesses of cotton and placed the top on. We went to a bee-man and he told us that we packed them too tight, and he told us to take the top off and put a chaff cushion on the top. CLIFFORD LEES.

Port Dover, Ont., Canada.

THE RESULTS OF STANDING IN FRONT OF THE ENTRANCE.

My mamma has three colonies of bees and an observatory hive. Some young ladies were looking at the observatory hive. They stood in front of the hive, instead of at the side, and a bee stung one of them by her eye, and a bee darted into another one's hair, and such a fuss she made! They all laughed to see her pulling her hair down to find the bee that did not sting her. Our bees are making very nice honey now from the new mint or pennyroyal. The young lady who was stung, on her way home had to cross the Wairoa River on a fallen tree. She fell off into the water, and joined the others in a hearty laugh. JESSIE HYDE, age 11.

Otau, Auckland, New Zealand, Feb. 4, 1886.

HORSES STUNG TO DEATH—A WARNING.

When pa had a few swarms of bees, a man tied two horses near them. Pretty soon they heard a noise. The men ran out and cut them loose. One horse ran home. The mare and colt were stung to death. The man was stung very badly.

Morocco, Ind., April 1, 1886. ELVA SKINNER.

Your letter is another one of the oft-repeated warnings, to be careful with our dumb animals near the bees. Frightful accidents have occurred, and will occur, so long as big folks, and little folks too, are careless. Only just the other day, while our new span of Clydesdale horses were cultivating near the outskirts of the apiary, a passing swarm of bees took a notion to alight upon the head of one of the animals. Joe, for that was the horse's name, kept switching his head at the bees as if they were flies. Had not "my pa" almost scolded the driver to make him realize the danger, and hurry the horses away, I am afraid our handsome big Clydesdales would have torn every thing to pieces, or possibly have shared as bad a fate as that of which you speak. ERNEST.

DOES MUTILATING UNSEALED BROOD ENRAGE THE BEES?

My papa has nine swarms. The other day, when he was looking at his bees, he broke a little brood-comb open that was in the milky state. This made the bees angry, and they chased the hens and chickens around the yard pretty lively for awhile. Some of the bees came to the house and got caught in a spider's web on the back porch. The spider came down expecting a fat breakfast, and he took the bee in a loving embrace, but went back in a hurry. Mamma said the bee stung him. He stayed hid for two or three hours; then mamma got him out to see if he was dead, but he seems to be as lively as ever. We have 74 hens and 158 chickens. I take care of the chickens and help take care of the hens. I keep account of the eggs laid. They laid 112 dozen last month. We set 17 hens on 233 eggs and hatched 176. The last of April, when papa took the sections off, he found one colony had put honey in some of them, both upper and under sides.

CLARA LINDSEY, age 10.

Harford, Susq. Co., Pa., May 24, 1886.

Yes, friend Clara, I think you are right in supposing that bees are sometimes enraged when their unsealed brood is mutilated to any extent. Yet it is quite possible that, when your father broke the comb, he jarred the bees on the frames. This of itself would be sufficient to anger the bees.—Your father evidently is an old hand at the poultry business, or he never could manage so many.

MINNIE DOES NOT AGREE THAT HONEY IS NOT GOOD FOR COLDS.

I have just been reading GLEANINGS, and in it I saw Miss Tessie Taylor's letter. It is very good for a ten-year-old girl, but I do not agree with her altogether about honey not being good for colds. It may not be very good for babies, but I don't think it would hurt grown-up people if they would not eat too much. I agree with you, that milk is good for the "honey-ache."

I will give Tessie my remedy for the earache. Take an onion, lay it in hot wood ashes till it is roasted soft; then take it out, squeeze the juice out, put a couple of drops in the ear, and put cotton in.

Last fall I helped my uncle to carry the bees in the cellar, and this spring I helped him carry them out again, and he is going to give me a hive of bees. I am going to help him put sections together this summer, and then I will write again and tell you how many I can put together in an hour. It is very kind of you to make such an offer to the ones who do well in putting them together.

Wilmot, Ohio, May, 1886. **Minnie Rhodes.**

Thank you, friend Minnie. I should be very glad to have you report the number of sections you can put together per hour. Do not get discouraged if, on the first 500, you can not fold as rapidly as little Ella. Remember, practice accomplishes wonders; and practice, if you try hard, will bring a prize. In the meantime let others try also. Perhaps I should say that a small wooden mallet is all you need. A light hammer will do tolerably well, but you will be working at a great disadvantage. Ernest.

HOW JASON CAUGHT HIS SWARM.

I have but one colony, and I will tell you how I came by it. A neighbor's boy and I, on the last Sunday morning in July, were taking a ramble in the woods after a rain-shower. After we were in the woods a few minutes, near by a large tamarack swamp, we heard a noise like the roaring of the wind just before a shower. We stopped to listen a moment, and I at once said that it was a swarm of bees, and, sure enough, it was. They were flying at tree-top height. We immediately began making a noise by whistling, and drumming on a little pail that I had with me, and they began to cluster in the top of a soft maple about fifty-five feet from the ground. I went back and got an old hive-saw and a long rope, and then returned to the tree, and then the fun began. I ascended the tree with saw and rope. At the second attempt I was successful in lowering them to the ground, and got them in the hive, and I did not get stung once. In a few weeks I transferred them to a chaff hive, and they worked rapidly. J. J. H.

Carlton Center, Barry Co., Mich., Jan. 16, 1886.

Thank you, friend Jason. I think you did well, if that was the first swarm you ever caught. You said you began to make a noise by whistling, and drumming in a tin pail. If the bees seemed to be arrested by the sound, and thereupon began to cluster immediately, it would go to prove that bees hear. In this connection I would like to ask the old folks, and little folks too, whether the drumming of tin pans does have an appreciable effect upon a swarm of bees, or is it all notion? Who will tell us? Ernest.

FOLDING SECTIONS AT 1½ CTS. PER 100.

Ma read me what you said about the little boys and girls putting up sections. I have put up hundreds for papa this season, and he gives me three cents for two hundred; but as I can work at them only when out of school I never kept the time. Papa says I do well, and am his little bee-man. I'm eight years old. Brother Willie can not work with the bees; for if they sting him he gets very sick. Papa has lots of bees, and is now taking honey. I help him with it too. **Freddie A. Ellison.**

Stateburg, Sumter Co., S. C., May 25, 1886.

FOLDING SECTIONS AT THE RATE OF 1000 IN TWO HOURS AND A HALF.

I put one-piece sections together at the rate of 1000 in two hours and a half. My brother's bees are doing well. He noticed them bringing in pollen the 20th of March, and noticed them working on fruit-bloom before the 20th of April. About half the swarms have started to work in the sections. As you said we could have our choice of any thing on the ten-cent counter, if we did real well putting sections together, if you think I did well enough, please send me some crystal starch polish.

Nettie H. Cranston, age 11.

Woodstock, Champaign Co., O., May 29, 1886.

HERE IS SOMETHING FURTHER IN REGARD TO THE SAME, FROM PEARL.

I put sections together at the rate of 1000 in two hours and a half. They were the one-piece sections. Brother Fred likes your foundation very well; the bees work on it better than on the flat-bottom foundation. Our plum-trees are hanging full this year, and the limbs are bending with them. We are afraid they will get stung. Our strawberries are getting ripe. We have a large bed of them. There was a hard storm here May 12th, and we had corn up almost large enough to plow. It rained so hard that it overflowed the field. It was the first time for about 30 years it had overflowed. As you said if we did well putting sections together, we could have our choice of any thing on the ten-cent counter, if you think I did well enough, please send me some crystal starch polish. **Pearl Z. Cranston.**

Woodstock, Champaign Co., O., May 25, 1886.

Thanks for the results of your trial. I must acknowledge that you both did extra well—nearly twice the speed of Ella, as recorded on page 415. I kind o' believe you both must be older, and that you had had considerable practice before at folding sections, or you could never have reached this speed. Let me see; little 7-year-old Ella folded 500 in two hours. For the first trial I think that was doing pretty well. At 3 cts. per 100, Ella earned 7½ cts. per hour, and you, Pearl and Nettie, 12 cts. each. Let me say just here, that a thousand folded sections in two hours and a half is nearly equal to the speed of one of our hands who is expert at folding sections. A little practice will surprise one at the rapidity with which he can work. Now if there is any 7-year-old boy or girl who can fold as fast as Nettie or Pearl, I should like to hear from you. At all events I do not wish any of you to strain yourselves in the effort to excel some one else. Master Fred's opinion about flat-bottomed foundation being inferior to other makes, accords with our experiments with the same about a year ago. We sent you both some crystal starch polish, as you requested. If you want it to chew as gum, I fancy you will have enough to last for a season. Ernest.

REPORTS ENCOURAGING.

SWARMING COMMENCED, BUT NO HONEY.

Bees in this section have wintered very nicely, and are in fine condition, if the weather would get warm enough for them to work. We have abundance of white-clover bloom and raspberry, but they do not work any on the clover, yet swarming commenced very early. Some began as early as the 9th of May. I have a case near here where four swarms have been cast from one hive. The prospects are very fair, if nothing prevents, that we shall have a fine season. We are ready, and will try to do our share, and know our little friends will do their part.

Coloma, Mich., May 28, 1886. S. Shoup.

SUGAR VERSUS NATURAL STORES.

I see by reports from different parts of the country, and also from your own apiary, that bees have wintered well, mostly on natural stores. Owing to an almost entire failure of the white-clover last season, probably one-third of all the bees in this section have died where artificial stores have not been supplied. One bee keeper of the "know-it-all" kind, who generally kept from 12 to 25 colonies in nice hives (but not movable frames), has lost every one. E. E. Cross.

Racine, Ohio, May 31, 1886.

500 GALLONS OF HONEY ALREADY FROM WAHHIAH, AND MORE TO COME.

The prospect for a large crop of honey is good at present. I have taken over 500 gallons from wahhiah, from 108 colonies, spring count, and increased to 145. The cat-claw has just commenced, and ought to give me 1200 gallons more. It is all nearly as white as water, and very fine and thick, and weighs 12 lbs. to the gallon. I had no loss in wintering; in fact, I have lost only one colony in three years. D. M. Edwards.

Uvalde, Texas, May 17, 1886.

HONEY FOR SUPPER-TABLE BY MAY 25TH.

I took off enough nicely capped section honey of this season's gathering yesterday to supply my family for supper. The entire crate (Moore's) from which it was taken will be ready to come off by the 1st of June, if the weather keeps favorable. Who can beat it? 3—F. J. Bostick, 9—13.

Greenville, S. C., May 26, 1886.

BEES NEVER IN BETTER CONDITION.

I never had bees in better condition than at present. First swarm of the season was May 20th, and two more since. This is pretty good for Northern Iowa. I attribute it not only to the favorable season, but to the feeding of a barrel of sugar this spring. C. A. Sayre.

Sargent, Floyd Co., Iowa, May 24, 1886.

WAS IT LARGE OR SMALL BUCKETS OF WATER THAT THE BEES DRANK?

The locusts are in full bloom at present, and bees are doing finely. It has been raining here for the past week, and we are having our share of the cyclone. I think the bees of Broers, spoken of on page 336, must be a "new" kind, to drink a bucket of water daily. May be it was a "wee" bucket, or perhaps they had tiny buckets hid away somewhere under their wings. I never saw bees work more on the dandelion than they have done this year. It came in bloom with us just after fruit-bloom.

Oakland, O., May 15, 1886. S. S. Craig.

TOBACCO COLUMN.

I commenced chewing about two years ago. A few days ago I thought I would would quit using tobacco. I heard that if any one would quit the use of it you would send a smoker as a present. If I ever commence using it again I will pay you full price for it. J. C. Stepheson.

Burlington, Burlington Co., N. J., Mar. 8, 1886.

How many smokers did you give away the last year, to those who quit the use of tobacco? It is surely pretty heavy on your pocket-book yearly. I don't use it and never did. C. F. Uhl.

Millersburg, Ohio.

All the smokers we give away to tobacco-users are noticed in Gleanings, for we always require a printed promise before sending the smoker.

I noticed in Gleanings (which is a very valuable journal, and a fine work all through), that you offer free to any one, who will give up the use of tobacco, one of your smokers. I have used tobacco for ten years, but I have given it up, and if you feel inclined to send me a smoker I shall feel grateful. I agree to pay you for the smoker if I ever use any tobacco again. J. Schautschik.

Serbin, Lee Co., Texas, April 26, 1886.

I used tobacco for 35 years. My wife often talked to me of its filth, and injury to my system. I thought several times I would quit the use of it; but not being able, in my own strength, to do so, I kept chewing until December. I can't remember what day, but shortly before Christmas, I quit chewing; and to-day, April 16, I am in perfect health. One of my neighbors told me you would send a smoker to any man who would abandon the use of tobacco. Here I am, trying to live a Christian life. I have given up all for Jesus, and a home in heaven. By God's assisting grace I mean to live right, so I shall be able to die right.

Paul Rudelbaugh.

Severance, Doniphan Co., Kan., Apr. 16, 1886.

A GOOD SUBSTITUTE FOR A CHEW OF TOBACCO; A TALK AFTER UNCOVERING A COLONY OF HYBRIDS.

Mr. Lewis.—"Mr. Barnhard, how do you manage to do any thing with such bees as those are?"

"I quiet them down with smoke."

"Where can any one get a smoker?"

"Of A. I. Root, Medina, Ohio. Do you use tobacco?" At this remark he put his hand in his pocket to let me have a chew, thinking that was what I wanted, but I replied, "I never use tobacco. A. I. Root will give a smoker to any one who will quit the use of tobacco."

He said, "I will quit the use of tobacco. I believe that tobacco is injurious to me; if I ever use tobacco again, I will hand you the money to pay Mr. Root for the smoker."

Brother Root, please send Mr. Lewis a smoker. I will guarantee the pay for the smoker if he ever uses tobacco again. Jacob Barnhard.

Denver, Newaygo Co., Mich., April 24, 1886.

OUR HOMES.

Jesus said unto them, I am the bread of life: he that cometh to me shall never hunger; and he that believeth on me shall never thirst.—JOHN 6:35.

WHO is there who has not at times thought it a little singular that Jesus should so often repeat the substance of the expression in the verse before us? Why should he call himself the bread of life? And I suppose others besides myself have at times thought it a little strange that he didn't choose an illustration a little more elegant in its form. Why should he link together the idea of a loaf of bread with the spiritual needs of the soul? Well, in this point as well as in almost every other in the Scriptures, you are most likely to get help in the study of the Scriptures themselves. When you feel like questioning the wisdom of using bread for a symbol, take your Bible and read a chapter or two before the place where this thought comes in, especially in the fore part of the same chapter where this occurs. The people had become wild with excitement over the startling miracles Christ had been performing. The craze was not so very much different from the way people act nowadays, especially in cities, where a great crowd collects over a comparatively small matter. In their enthusiasm they followed him away off in the country—away from bakers' shops, or any other place where provisions were sold; and with such a crowd as five thousand, even the farmhouses (if they had any such things in those days) would not be likely to supply their wants. The people became hungry and weary, and it was a long way to their homes. The tender heart of our Lord was touched by their wants; and especially was he touched because they had apparently forgotten every thing in their desire to follow him. You know how often he enjoined mankind to leave all and follow him. Well, these people had left all and followed him; and even though their motive in so doing was not one of a very high order, there they were. Very likely a great part of them would have been equally ready to follow something else of a different character; but our Savior does not seem to have considered this; he only feels they are a part of humanity—that humanity whom he loved and whom he came to save. He did not feel at a loss what to do under the circumstances, nor did he doubt for an instant that the Father would honor his request by giving him power to provide bread miraculously. This is evident from the question to Philip.

By the way, there has always been something wonderfully comforting and strengthening to my faith in these little passages where the Master speaks to his disciples in that pleasant, familiar way. We could hardly call it joking, but it was a little bit of pleasantry when he says in that wonderfully kind and familiar way to Philip, "Whence shall we buy bread that these may eat?" Poor Philip! like all the rest of us he was utterly unable to comprehend for a single instant the resources at the command of his Master. Jesus was evidently trying to teach him faith by the question. Why didn't Philip reply, "Lord, thou hast every thing at thy command. We know from what we have witnessed that the whole universe is subject to thee. Speak the word, and they shall be fed"? Instead of making such a reply as that, Philip simply answers, "Two hundred pennyworth of bread would not be enough to give every one a little." Two hundred pennyworth would be equivalent to something like two hundred days' work. Who is there who is going to advance this great sum? Andrew ventured, at this crisis, the information that there was a boy somewhere around with five barley loaves and two small fishes. This boy had evidently had an eye to business, even through all the excitement; and when they started out he wisely concluded that, before they got back, there would be a chance to sell eatables at a figure that would afford a good margin of profit. He probably was not in a hurry; he was going to bide his time, and then get up a corner in the provision market. It seems that Andrew was about as lacking in faith as Philip, for he ventures to suggest, at the close of his piece of information, that five loaves and two fishes didn't amount to very much when there were five thousand to be fed. No one seems to have had the slightest conception of what was going to happen. Now witness the wonderful beauty and simplicity of the manner in which the Savior goes to work. Whatever he did was to be done decently and in order. No rabbles or greediness was to be the result of any miracle that he performed. Before telling what was to be done, he directed that the vast company be desired to sit down upon the grass. They sat down in groups of fifty, probably with passage-ways between them, so the disciples could wait upon them in an orderly and systematic manner. The whole company obeyed him. Why should they not obey one whom they had seen perform such wonders?

Years ago, here in our little town of Medina it was decided to have a free dinner one Fourth of July. Everybody who came, no matter who, was to have a good dinner, not a penny to pay. The project was a kind one, and the good women who had it in hand labored early and late to make it a success. Officers were appointed to keep order. How do you suppose it turned out? Why, after it had been advertised in the papers, the ignorant, beer-drinking rabble for miles around got hold of it and rushed in in such a body that the officers were powerless to preserve order. The tables were emptied before they were even fully set; and while respectable people held aloof, these greedy ones gorged themselves and filled their pockets, and trampled the rest under foot. So much for a free dinner. How differently the Master managed it! Here was a miracle in good earnest. Five thousand people witnessed it. They had the bread and fish in their hands. Skeptics might, doubtless, claim that it was an optical illusion; they did not have any bread at all, they only imagined it. But the trouble is, they ate of it and were satisfied. It would have to be a pretty stupendous optical illusion to convince a hungry man he had been fed when he hadn't. They had tasted the food, each and every one of them; they saw it miraculously multiply with their own eyes. If there were any doubting Thomases among the crowd who felt like demanding something plainer before they would believe, they had got it. I think I am safe in saying that there was not a single doubter among that whole five thousand. From that time forward they had faith in Jesus — that is, they had faith in his power to provide free dinners.

Now, I need not tell you that this was not what the Master was striving for. He felt touched because of the hunger and faintness of so many, and he felt a thrill of joy in being able to provide for these temporal wants, no doubt; but this was by no means the end and object in view. He came not, simply to give bread to the hungry, but he came to save sinners. After the people had been fed he sought to teach them spiritual lessons. Why did they want to make him king? Doubtless because they rightly supposed he would be better able to give them free dinners than any other king the world contained, and this was the great sum and substance of their aspirations. Would free dinners every day have made them better men? Some of our great cities have tried the experiment, and perhaps those who had the matter in charge came out a little sadder as well as wiser when the experiment was over. Dear reader, would it make a better man of you to give you a *free* dinner every day? To be sure, not. It would, without question, do you harm. "By the sweat of thy face shalt thou eat bread." This is the law of our being, and it has never been recalled. The miracle answered its purpose, however, and the people flocked to the other side of the lake to find this wonderful prophet. They were in haste to see him use this wonderful power again. They even suggested a variation in the programme, and thought that manna sent down from heaven in the good old way Moses used to manage it would be about the thing. Jesus strove to turn their thoughts to spiritual things. His life was a life of self-sacrifice, and no true life was possible for them unless they took up a similar life of self-sacrifice. Said he in substance to the multitude, "My friends, it is not bread you need to make you happy; it is all very well so far as it goes, but it won't answer at all. My Father giveth you the true bread from heaven." And again, "For the bread of God is he which cometh down from heaven, and giveth *life* to the world." They did not comprehend very much what he meant—probably they didn't care; but they replied promptly, "Well, give us this bread;" or, in other words, "All right; let us have this bread you tell about; we are ready for it." They thought they were, but they were not, any more than you and I are when we in our prayers ask God to bring us near to him, even though the way be through crosses and trials. Now Jesus replies to them, "I am the bread of life; he that cometh to me shall never hunger; and he that believeth on me shall never thirst."

His meaning was something like this: They were greedy and selfish; their principal thought was of something to eat, and how to get it with the least possible exertion. Their wants, their pursuits, and their ideas of happiness were low and animal; they had no idea of self-sacrfice; they had no idea of bearing burdens for the general good of humanity. He calls them to think of higher things. He tells them if they devote their lives to the pursuit of food and drink, and something to wear, they are seeking for that which is short-lived and unsatisfying. "Labor not for the meat which perisheth," he says to them, "but for that meat which endureth unto everlasting life." To make it plainer, let us consider humanity as it grows up untrained. We sit down at the table. The whole family are present, perhaps aunts and cousins. As soon as the blessing is asked, Huber calls out, "I want some beans." Now, I do not want our children to grow up selfish, and thinking of themselves first; and as I rebuke the little fellow, whom we all love so much, I state it to him in this way: "Do you want some before cousin Mabel has any?" He sees the point at once. Cousin Mabel is a guest for the time being, and his own good sense, and I hope his former teaching, tells him that a guest should be treated with honor and preference. When the question is fairly before him, whether he shall have some beans first of any one, even to the exclusion of cousin Mabel, whom he loves, baby even though he is, he sticks his tongue off to one side of his mouth, and casts his eyes downward a little, ashamed of himself. Perhaps he does not answer in words; but I know by his looks that his little thoughts are running something in this way:

"No, papa, I do not want to be waited on before cousin Mabel is. I want to be a good boy, and not a selfish one."

Now, this multitude to whom Jesus was speaking was a selfish multitude. They were in the habit of being greedy. Many of them, perhaps, were guilty of gross crimes in giving way to these untrained animal impulses. Jesus tells them that, although he could, by his mere volition, call forth bread in unlimited quantity, it would not be for their own good. "Come, follow me," he says; "don't be thinking all the time of something to gratify your own selfish appetites. Taste the joys, and experience for a little time the blessedness of laboring for the good of others. Follow me, and I will make you fishers of men." Now, if you will read this whole chapter through, and all along through John, you will notice how hard Christ labored and taught to give them a glimpse of the blessedness of a life devoted to the good of the people, or to the saving of souls, if you choose.

We are most of us seeking pleasure in some form or other in this world. We are thinking of that which will give us the most happiness; and in a certain sense it is right we should do so. We are human and full of wants, and full of likes and dislikes. We like to enjoy ourselves, and we like to give full sway to the faculties God has given us in the enjoyment of pleasure. Now, what is it in this world that really satisfies us most? What is true happiness? The subject came up recently at our young people's prayer-meeting. I told them that the happiest hours I had ever spent in my life were in going to teach a Sunday-school, a few miles off in the country. At first I used to go with a horse and buggy, and I found a good many young people in our town who liked to go with me. Almost any of the boys were pleased with an invitation to go to the Sunday-school Sabbath afternoon. Now, in our town there is quite a tendency among young people to go out buggy-riding Sunday afternoons. Our livery-stables do a larger businsss Sunday than any other day of the week, and I soon began to be afraid that the buggy-ride had more attractions to many than the Sunday-school work itself, so I decided to go on foot, that my motives and example might be in no way misinterpreted; or I walked five miles and back again every Sunday after two o'clock, for Christ's sake. Need I tell you that I enjoyed going on foot ever so much more than I did when I rode? When the weather became stormy, and the walking was difficult, or perhaps when I was compelled to take an umbrella, I started off in the rain, then I specially enjoyed it. Yes, the happiest hours I think I ever enjoyed were when I plodded along through the rain to meet the circle of boys and girls that I was sure would be on hand to greet me. Would I ever get tired of such work? I am sure I should not. I was weary in body, perhaps, many times, but elevated in spirit. Did I ever doubt the presence and the promise of the Savior at such times? Never, for an instant. Now, then, how does this tally with the text, "I am the bread of life; he that cometh to me" (that is, he that comes to me for enjoyment and for happiness) "shall never hunger; and he that believeth on me" (he that comes to me in faith, and drinks of the water that I have to offer all my followers) "shall never thirst"?

May I tell you a little piece of good news? This Sabbath-school was discontinued at the time of my father's sickness and death, and it has never been started up again since. Only this week a message has come to me that my old friends in Abbeyville, and perhaps some younger ones that have grown up, would be glad to see me every Sunday afternoon again, if I should care to go. Need I tell you that my heart bounds at the thought of it?

Several of my former pupils are now working for me, and I am glad to say that most of that Sabbath-school are now enrolled as members of churches of different denominations. Do you wonder when I tell you that I look at these young people almost as if they bore some sort of relationship to me? Some of them are married, and have homes of their own. They often bring things to me to sell. Do you think it strange that I almost always feel like buying whatever they have to offer, or giving them the preference because they used to be my children? Well, now, suppose your work in life is such that a great circle of people have learned to look to you more or less for the bread of life, or have considered you as in some sense a spiritual adviser, what effect should it have upon you? As I consider these things, that old prayer that I have told you about so often comes up of itself, "Lord, help; Lord, help." This prayer comes up because I realize how very, very human I am.

The people wanted to make Jesus king after he had fed the multitude. Some one has said that the reason why they preferred him for king to anybody else just then was because they thought it likely he would give his subjects a "free dinner" *every* day. This was far from his intention. It is true, he wanted to reign in their minds and hearts as king of the truth; but far, oh, very far was it from his thoughts of having any thing in common with an earthly ruler. His little band of followers, and those whom he commissioned to perform miracles as he did, were very common, humble people. I have sometimes thought they were dull people, slow to comprehend and slow to believe. When he told them to beware of the leaven of the Pharisees they thought he was chiding them because they had forgotten to put any bread in the boat. When he told them about coming into the world to save sinners, Peter declared that he should do nothing of the kind, and when he told them of his approaching death on the cross, not one of them seemed to get a *glimpse*, even, of his mission and his office. It has been a comfort to me to think they were such commonplace individuals. If Jesus loved them and called them his own, may it not be possible that he will love *us* and call *us* his own in that great day? Jesus so loved the world that it was a pleasure to minister to them. No doubt he felt a thrill of joy when he ministered to their natural hunger; and who can tell of the joys that cheered his in many respects sad life when he saw glad souls rejoicing because of this spiritual bread which he was so ready and willing to give? Now, dear friend, is it difficult for you to understand or comprehend the great truth that he was endeavoring to teach when he said, "I am the bread of life"? Is it possible that you, my friend, have been striving and worrying and fretting over this great problem of furnishing bread for you and yours? If so, have you, too, forgotten the bread that Christ can give, and of the water of life that he is glad to furnish? He said again, "I am the living bread which came down from heaven; if any man eat of this bread, he shall live for ever." We are told that even his chosen disciples were stumbled at this latter saying. Many called it a hard saying, and said, "Who can hear it?" And some went back and walked with him no more. Is it not so, even to-day? Religion is becoming fashionable. Many are attracted. But some, I fear, after they get to the true source, and find it to be a life of self-sacrifice and hardship, a life of incessant toil, with many times little reward and no thanks, they are offended and turn away. Thank God, however, there are some like Simon Peter, who, when Jesus asked if he too would go away, replied, "Lord, to whom shall we go? Thou hast the words of eternal life." And I believe a good deal as

Peter did then, that one who has once tasted of the bread that Jesus gives will nevermore find peace or enjoyment anywhere else.

Not very many mornings ago it was wet and rainy. I had on my rubber boots, and was chasing about in the grass and mud, looking after some of our "small boys," getting things ready for the wagon to start out as soon as the clouds promised to clear away, when an old friend accosted me something in this way: "Well, old fellow, may be that is *your* way of enjoying yourself; but if I owned such a factory as you do, I don't think you would catch me chasing around in the mud and wet after them sort of chaps."

"Well," said I, "if you were running such a factory, what would you do—put on some fine clothes, and sit around and talk with big men?"

"Well, you may just bet your last dollar *I* would."

After he had gone I thought it over. Perhaps he was right in thinking I bestowed more pains and bodily strength on some of my boys whom I pay only six or seven cents an hour than I did on those who have large salaries, and work by the year. Was it right? I thought it over, and concluded, "Yes, it *is* right. The older ones don't need me. Their minds are already formed; they are trusty, and can take care of themselves. These I have been chasing after have hardly started in any direction, but they are growing rapidly day by day, and are fast forming habits, either good or bad. If, by chasing around in the wet, and, may be, taking hours of my time, I can get them started in good ways, and, may be, instill important truths in their little minds, I am content; nay, more: while I am doing this and looking out for the lambs of the fold, I know that He to whom I belong will take care of the business, the money, and all else pertaining thereto; and, furthermore, I have this written promise that there is "henceforth a crown laid up for me, which the Lord, the righteous judge, shall give me at that day; and not to me only, but unto all them also that love his appearing."

Besides, I am happy, very happy, chasing around in the wet with my muddy boots and old clothes. Those who find comfort in expensive clothing and ease may have them. I do not envy them a bit. Give me the clouds and the rain, the blue sky and the bright sunshine that comes with it; give me the free open air, with God's love welling up in my heart, and these little friends to look after and to care for, and I am content. I am his and he will take care of me; and, most glorious of all, he will take care of *them* if I succeeded in bringing them to him.

CIRCULARS RECEIVED.

The following have sent us their price lists:

H. P. Langdon, East Constable, N. Y.,—an advertising sheet of bee-supplies.

F. J. Crowley, Batavia, N. Y., a 12-page circular of bees and queens, and apiarian supplies.

C. A. Stillman, Hornellsville, N. Y., a 6-page list of bee-supplies.

John H. Howard, Holme, near Peterborough, Eng., a 60-page price list of apiarian supplies. It is fully illustrated, and it gives one a good idea of the present state of apiculture in England.

I am being asked my opinion of the new circulars Mrs. Cotton is again sending out quite plentifully. The statements she makes, and the prices she charges for the goods she sends out, would, in my opinion, forbid her being classed with our regular supply-dealers, to say nothing of the strings of complaints against her that have filled our bee-journals for years past.

PURE HONEY.

MORE CONCESSIONS FROM OUR FRIENDS OF THE PRESS IN REGARD TO THE FALSE STATEMENTS ABOUT THE HONEY IN OUR MARKETS.

WE clip the following from the *American Grocer* of June 9:

> In March the *Christian Union* printed an extract stating that honey was adulterated. The assertion brought forth a letter from an Illinois correspondent, stating:
>
>> There is absolutely no such thing as manufactured or artificial comb honey, sensational newspaper articles to the contrary notwithstanding, and one when buying it can be almost as sure of getting a perfectly pure article as if buying fresh eggs or strawberries. In years past, when liquid or extracted honey was worth as much again as it is now, it was largely adulterated by city firms that repacked it for the retail trade; but since its price has fallen to from four to eight cents a pound, this abuse is the rare exception and not the rule.
>>
>> As long as four years ago, Professor J. Hasbrouck, in order to ascertain the truth regarding the alleged prevalence of this nefarious practice, procured a large collection of specimens of honey from all possible sources—from commission houses dealing exclusively in honey, from others with a miscellaneous stock, from grocers and marketmen, from the tons of noted bee-men, reporting suspiciously large average per colony, and from small consignments of obscure producers. Besides these, he received a great many packages for analysis from persons made suspicious of honey by such paragraphs as yours. He examined all carefully with the polariscope, and in every case found every box of comb honey, and every package of extracted honey not repacked in the city, absolutely pure, with but a single exception — one sample of comb honey containing a small percentage of glucose syrup, which had been fed the bees to keep up brood-rearing during a dearth of pasturage.
>
> The letter was sent to Lyman C. Root, editor of *Bee-Keepers' Magazine*, an expert, and for whose integrity the *Christian Union* gladly vouches, though among bee-culturists he is so well known that he needs no voucher. He states that "the points above given are well taken," and says:
>
>> The facts, in brief, are these: To manufacture honey-comb, fill with honey, and cap it over, is simply an impossibility. Many strictly reliable individuals, as well as leading bee-keepers' associations, have at different times offered large amounts of money for every pound of such manufactured honey. I think I am safe in saying there is not a more strictly pure article of food used throughout the world than our comb honey; and, indeed, at present I might include our liquid honey also — unless it is such as is sometimes tampered with after it passes out of the producer's hands.
>>
>> We have State and county organizations in nearly every State of the Union, and all bee-keepers, as well as dealers generally, are closely watched, and our interests guarded in the closest manner.
>
> If the press generally were as diligent as the *Christian Union* in refuting false charges regarding the food supply, there would soon be an end to sensational reports of adulteration, from press and from pulpit.

The above is so good, and so right to the point, we can easily excuse the mistake our friends of the *Grocer* make in calling our good friend L. C. Root the editor of the *Bee-Keepers' Magazine*. No more able man than L. C. Root could have refuted the false statement; but if we are correct, his field is bee-editor of the *American Agriculturist*.

JUST HATCHED.

AN ALARMING CASE OF BEE-FEVER.

WHAT, a queen? No, not a queen nor a queen's husband nor a queen's servant, but an enthusiastic apiarist; and already they are saying, "He is going to succeed." Well, I prefer success, and hope that their prophecy is correct.

I am by nature a chicken-fancier; and always, when I talked chicken, my wife would talk bees. I always thought that, had I invented the bee, I would certainly have left out one point, or else made it blunter; but now I think that very *ing*redient the finest point in the entire invention. Why, I now get shouting happy in less than half a second, when my mind is brought suddenly to contemplate this point in the honey-bee.

A few days ago I came to the knowledge of the fact, that when she whom my children call ma was a little black-eyed girl she had her playhouse under the same tree with the bee-hives, and that she amused herself by the hour in watching their industry. I said to myself, "Now I understand my wife's enthusiasm and devotion." I got into my buggy, and started for the most successful apiary in this part of the State, to buy, for my wife, one or two first-class colonies. On my arrival I found the busy little proprietor transferring and remodeling hives. She had help, but not enough, so I joined the party, and for three days I was one of 'em. I caught the bee-fever, and caught it bad; so bad, indeed, that before the sun went down the first day an order for two chaff hives in the flat was written to the editor of GLEANINGS.

The work went on, and the fever raged, and rages yet. In a very few days the hives came, and they certainly were in the *flat;* and for a number of hours, as we studied the "great many pieces," we felt a flattening influence coming out of the flat hives which flattened us flat. How I wished for the "model to work by," or for a printed slip giving light on such parts as are hardest to guess out!

But we have got them together at last, and they are gems, and gems, too, which make the old apiarists sick, as they think of the houses their bees live in. I find myself on the wing, and, like any thing else just hatched, I find it a difficult matter to alight; but I have caught a twig, and will rest for awhile.

Hilliard, O., June 9, 1886. JAS. R. RICKETS.

Why, friend R., you are located near by that energetic and enthusiastic little woman Mrs. Jennie Culp; and if you helped her three days, no wonder you got the bee-fever, for she is one of the most successful honey-producers in the State of Ohio.—No wonder you had difficulty in getting that chaff hive in the flat set up, without a model to look at, or an A B C book.—I suppose now that she whom your children call "ma" is happy too; and, by the way, I can not think of any happier sight on this green earth of ours than a husband and wife who love bees and chickens, and who delight to work among them, studying God through his works as the hours go by. May much peace and great happiness be with you two, friend R., and don't fail to tell us more about it. If the good wife should feel like putting in a word now and then also, be sure to encourage her in so doing.

NOTES AND QUERIES.

A CHANCE TO GET A SWARM OF CYPRIAN BEES FOR NOTHING.

I have a strong colony of Cyprian bees, *pure.* The queen was sent to me last summer. I will give the colony to any reader of GLEANINGS who sends in his name first, if the one sending will pay for hive and trouble of packing, which will be about $1.00. These bees are so very cross that I do this to get rid of them, and send them where I may never see them again. I got more stings in five seconds yesterday from this colony than I have received from my Italians of over 575 colonies in 2 years. They stung me so that I was speechless for over 20 minutes. Smoke only makes them worse. Who wants them? If no one will take them I will brimstone them. First name that comes gets them.

F. BOOMHOWER.

Gallupville, Scho. Co., N. Y., May 19, 1886.

ALSIKE CLOVER—EARLY CROP FOR HAY—SEED.

We have some alsike, sown one year ago. We want to take a crop of hay early. Will it yield a crop of seed afterward, the same as we do with the common red clover? C. F. UHL.

Millersburg, Ohio.

[Friend U., you can get a nice bloom on your alsike, if you cut it off early, just before it begins to blossom; but you will get only a partial crop of seed in this case.]

PRICKLY COMFRY AS A HONEY-PLANT.

Last spring I bought a plant from a bee-man in New York. It is called "prickly comfry." It was recommended as a honey-plant. This spring it is all blooms, and in the bottom of the cups there is a drop of pure honey. Can the bees get at it? It seems too deep for their little bills. It is surely a great honey-plant. I wish I could send you a sample bloom. J. J. B. MCELRATH.

Centre, Ala., April 28, 1886.

[We have a large fine plant of the prickly comfry now in bloom in our garden. Like the one you have, there seems to be considerable honey in the blossom; but as yet, the bees do not seem to have found it.]

ALSIKE, HOW TO GROW.

I see in the last GLEANINGS that Dr. Miller can not get a good stand of alsike clover. I was born and raised on the estate in Sweden whence it has its name—Alsike, and happen to have an old man at work for me here, from the same place; and inquiring from him how they raised it at home he said that unless it is sown just as snow melts away in spring it will certainly be a failure. He said further that he has many times sowed on the snow and with the best results. F. G. LINDBERG.

Port Orange, Fla., May 31, 1886.

BROOD IN SECTIONS.

On page 128 of A B C you state: "I have never seen any pollen nor any eggs carried into a frame of sections where separators were used."

Well, I am only a novice, but I have seen young bees in sections. In 1884, out of over 400 sections placed on my hives I found three or four containing young bees sealed over.

Rabun Gap, Ga., May 24, 1886. W. R. CURTIS.

[Your experience is very unusual, I think, friend C. Since the above was written in the A B C, some cases have been reported where the queen got into the sections, even though separators were used; but I think the rule as given in the A B C book has comparatively few exceptions.]

OUR OWN APIARY.

IMPORTED ITALIANS THE BEST HONEY-GATHERERS.

THE white-clover bloom is now fairly upon us, and the bees are just beginning to drop in at the entrance. When honey is coming in freely it is only necessary to watch the entrance of the hives to determine what colonies are the best workers. In a large apiary there are always some colonies that are much better than others, and a glance at the entrances during a flow of honey very quickly, and very correctly, too, shows whether the bees of this or that colony are good workers. At the entrance of good honey-gatherers the bees may be seen to dart out and in in quick succession. When there is a copious flow of nectar the bees will often drop a few inches from their entrance, preferring to crawl in for the remaining distance.

Hearing the bees roaring over my head one forenoon as I neared the apiary, I determined to see what were our best working colonies in the apiary. Some stocks were very conspicuous for dropping at the entrance—much more so than some of their neighbors. In turn, as my attention was arrested by that peculiar popping in and out at the entrance of some of the colonies, I examined the slates whereon was tabulated the previous record of the colony, together with the kind of queen. Now, I confess I was greatly surprised at the uniformity of results indicated by the slates. What did the tablets say? The bees that were the most industrious—those that had the most honey in the hives—were the progeny of *imported Italian queens*. "Oh!" but some one says, "you have a lot of imported queens you wish to dispose of." But, look here, my friend; I did not *know* when the dropping at the entrance of any particular hive attracted my attention that said colony had an imported queen. In fact, with a few exceptions I do not know nor can I remember what kind of a queen each colony possesses, out of the 420. I rely entirely upon what is said on the slates. The two Kimbers have the care of the apiary, and I go among the bees whenever I can find spare moments from the factory. Now, without the aid of memory or any previous knowledge, I could point out with scarcely an exception a colony that was then in possession, or did possess, an imported queen. By referring to the slates I found that I was correct. So surely did the progeny of the imported queens make themselves manifest at the entrance, that I could scarcely believe my eyes when reassured by the little tablets. To show you that I was not mistaken, a number of the hives in question were opened. The combs, many of them, were nearly full of honey, and the edges of the cells were whitened, and little burrs of wax began to appear. There was only one colony whose bees were not the direct progeny of an imported queen that especially attracted my attention. But the slate showed that it was an extra nice select tested queen, bred from an imported mother.

Mr. Kimber, our apiarist in charge, says for two or three seasons he has noticed, as a rule, a marked difference in the energy of bees from an imported Italian queen, over the progeny of queens of the same race, bred in this country for three or four generations back. Several days ago he had mentioned this superiority to me, but, thought I, "It's all in your eye," Subsequent investigations, as recorded in the foregoing convinced me that he was about right.

Again, you will remember that our colonies were wintered on select combs of nice sealed honey. To obtain these combs, a number of colonies were set apart, some of which were the progeny of imported and some of home-bred queens. Of this lot, the colonies that produced the most honey were from imported queens.

Whatever may be the valuable qualities of queens bred in this country, whether by selection or not, I do not believe we can improve upon those reared in their own country, with the advantages of native climatic conditions. The dry climate of Italy is bound to produce good energetic worker-bees; or, in other words, it is the old question of the survival of the fittest—sink or swim.

Our friend Doolittle, in a recent number, does not speak very favorably of the imported queens, and yet he says, in the same article, that he never has had more than one imported queen in his apiary. He bases his judgment on this one imported queen, and from the daughters not only of this queen but from other imported queens. We import a hundred or so of queens from Italy every season, and their bees have been watched side by side for years in our apiary with the progeny of home-bred queens; and, as a rule, the imported have demonstrated their superiority.

CARNIOLANS POOR HONEY-GATHERERS.

While I have been watching closely other colonies, the Carniolans have received their due attention. I am compelled to say that they are poor honey-gatherers; in fact, when honey has been coming in tolerably well they have barely supported themselves, and yet they have been given every advantage. The colony has not yet been divided, as is the case with all our other stocks, and, in consequence, it is the strongest colony we have; and yet small nuclei of Italians have actually more pounds of honey than this swarm. When the mother of this swarm was received, the cage in which she came was marked "very fine." If she is one of the best, I do not believe that we wish to invest very largely in the mediocre. The other Carniolan swarm which we have is no better. Several, whom I do not now remember, claim that they are great comb-builders. As honey has been coming in freely, I inserted two frames of foundation between two frames of brood of the Carniolan swarm; at the same time in like manner frames of foundation were inserted in nucleus Italian swarms. These frames were given nearly a week ago. The Carniolan swarm has scarcely done any thing yet at their foundation. Hardly 48 hours had elapsed when the Italian nuclei had pulled theirs about all out. The action of the Carniolans at the entrance is sluggish, and, to say the least, the bees are lazy. I do not claim that the same characteristics are true of all Carniolans, but I do insist that they are true of two colonies of this race in our own apiary. It is not my purpose to injure the trade of those who have Carniolans for sale, however much it may look that way; but I wish to urge the friends to be cautious about investing too largely in them.

SALT IS A NECESSARY ELEMENT FOR BEES.

On page 502 of this present issue, D. C. Underhill says, quite vehemently, that bees do *not* need salt. You remember some time ago I told you that the application of salt effectually kills the weeds at the entrance of hives. This spring, as usual, the salt was sprinkled in front of each entrance, and the result is that all our hives have nice clean entrances. What has this to do with salt for bees? In the evening, after the first rain has wetted up the salt, bees may be seen at the entrances licking the salt. Now there is something about this salt that they like. Again, for several years we have had an atmospheric-jar feeder of water located in the center of the apiary, that the bees might come there and drink; but the bees scarcely ever went near it. Finally it occurred to the apiarist to add a little salt to the water. The result was very satisfactory; for at any time now the bees may be seen at this jar, taking a good drink. If you don't have success in inducing your bees to drink water from a feeder, add a little salt, and note the effect. ERNEST.

GLEANINGS IN BEE CULTURE,
Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JUNE 15, 1886.

But the very hairs of your head are all numbered.--MATT. 10:30.

BINDERS FOR GLEANINGS.

OUR enterprising friends, Barrett & Co., have lately given us a beautifully embossed binder, very much handsomer than the plain ones we have sold for so many years. The best part of it is, the price is just the same as it has always been; viz., 60 cts.; by mail, 12 cts. extra for postage.

HYBRID BEES VS. FULL-BLOOD ITALIANS.

WE have for several seasons had a customer who orders hybrid queens with pounds of bees. When we are out of hybrids we send him untested Italians instead; but he says he would rather have the hybrids, because he has better luck with them. Is it *possible* we are making a mistake in driving all of the black blood out of the country ?

ANOTHER BEE-BOOK.

AND now it is the Rev. W. F. Clarke who has written a book, and it is published by Jones, Macpherson & Co., of the *Canadian Bee Journal.* This book is unlike any other bee-book, inasmuch as it is all poetry. It has not made its appearance yet; but the simple fact that it comes from the pen of W. F. Clarke is a guarantee of its being a valuable addition to our bee-keeping literature. The price will be 25 cts. per copy, or five copies for one dollar.

THE $1.50 HONEY-EXTRACTOR.

SEVERAL of the friends have written in regard to this, as it has been advertised somewhat extensively. To be able to reply understandingly we sent and got one; but, when received, it proved to be no honey-extractor at all, but the *inside* of one only, and that inside was *in the flat.* We did not take the trouble to try to make an extractor out of it according to the directions. Perhaps some might succeed with it, and it might be considered right to charge $1.50 for the arrangement; but it certainly is not right to advertise such a thing as a *honey-extractor.*

BEE-KEEPING FOR THE CLERGY.

FROM the *Congregationalist*, of May 20, we take the following clipping, written by our old friend and pastor, A. T. Reed, formerly of this place, now at Chardon, O. We started him in this pursuit, and the following tells how he has succeeded:

> WHY MINISTERS SHOULD KEEP BEES.
>
> *For the pecuniary profit.* One minister, year before last, made $50 from four colonies; last year, $20 from four, and developed them to twelve.
>
> *For health.* It is the kind of exercise especially adapted to the clergyman's needs; outdoor, light, absorbing.
>
> The bees need the most attention in the time of the minister's greatest leisure—say from May to September—and necessitate no thought or care in the winter months, when the minister is the most occupied.
>
> *For study of insect life.* The instinct of bees is of the highest order, and is a source of wonder and admiration. With a colony of pure Italians in your back yard, you may daily watch almost every process of bee-industry and life, immediately under your eye, without danger, and with a charm of enthusiasm, once experienced, never to be forgotten.
>
> *For illustrations.* There are more sermons in bees than in trees, stones or running brooks.
>
> *For discipline.* To receive the occasional inevitable sting with equanimity, quietly place the sting under the microscope, in the interest of science, and admire and commiserate the bee who thus gives his life for the protection of his commonwealth, is to acquire a self-control greater than his who taketh a city, and a philosophy surpassing the Stoics. The minister who can conquer the 40,000 mad bees of a single colony will develop a spirit of self-control, persistence, heroism, and generalship not without its use in the pulpit.

HOW TO MAKE FOUNDATION.

OUR machinist who makes the comb-mills has made a great improvement in the knives for cutting the rolls, and the process is somewhat changed also, so that our new comb-mills are much superior to those we have formerly sent out. Our old 10-inch comb-mills would not turn out as thin section foundation as mills specially made for the purpose; but the improved 10-inch mill will now make as nice an article of thin foundation as the 6-inch mill. The 10-inch mills in our wax-room now make both thin and heavy foundation; but to do this the rolls should be *perfectly* clean. In fact, you can not do satisfactory work on either thick or thin foundation unless the rolls are free from particles of wax, which will gradually work into the cell-walls. Clean the rolls often, or you will become disgusted with the whole business.

HOW TO CLEAN FOUNDATION-ROLLS.

The easiest and most expeditious way of cleaning the rolls that we have tried is turning a jet of steam on to them for five or ten minutes, or till the rolls feel hot to the hands. While the steam is blowing, the rolls should be turned backward and forward. The action of the steam is to melt the particles of wax, and then to blow it off in fine dust. Next turn off the steam, and then scour with a brush and boiling soapsuds. When again you run sheets of wax through the rolls as thus cleaned, you will be surprised at the improvement.

The one great objection, however, to the use of steam is that few are so situated as to be able to use it. Our girls have cleaned the rolls with gasoline with very satisfactory results, as benzine or gasoline absorbs wax very readily. As the latter method is not quite so rapid, and would also affect our insurance, we use and prefer the steam, though to the majority of our friends who have comb-mills the gasoline will be found the most convenient.

I need hardly tell you that the utmost care is to be exercised in handling gasoline. In washing rolls, or even in having an uncorked bottle around, be sure that no lighted lamp or candle is within several feet; and if you do not do the washing in the open air, open the doors and windows wide, so that the explosive vapor may be blown out before a lighted lamp or match is brought into the room.

P. S.—Our new improved mills will be the same price as quoted in our price list.

REDUCTION IN THE PRICE OF BEES AND QUEENS FOR JULY.

Owing to the continued favorable weather we have decided to allow a discount of 10 per cent over and above all other discounts given in our price list on all bees and queens, excepting on our untested queens when ordered alone; but if with pounds of bees, or colonies, the above discount will be allowed on them also.

48 IMPORTED QUEENS ALIVE AND IN GOOD ORDER, OUT OF A SHIPMENT OF 50.

We have to-day unpacked our first shipment from our friend Bianconcini, for the season, with the above good result. These are all young queens, raised this year; in fact, they were reared expressly for our trade. Now, we have in our apiary 25 imported queens, shipped last fall, and wintered over. These will be 10 per cent less than the lot just received.

EIGHT TONS OF WAX MADE INTO FOUNDATION UP TO DATE.

The low price at which we have been offering foundation has given us another big trade in our foundation department. We have used eight tons of wax so far, and as yet we are just in the height of the honey-flow. Two or three years ago we made fourteen tons of foundation. Our business is still booming in other departments, though we expect trade will drop off soon. Goods of all kinds are going off with little or no delay.

THE NEW EUROPEAN SILVERHULL BUCKWHEAT.

Our friends may remember that we some time ago mentioned the fact that Peter Henderson claimed to have something in the way of buckwheat quite superior to any thing heretofore disseminated. We sent at once for a bushel of the seed, for a sample. It has a smaller-sized grain, quite distinct from any thing that we have ever before handled; and we are happy to say that we have been able to secure a lot of 25 bushels of this new buckwheat. Instead of $5.00 a bushel, however, the price charged by Peter Henderson, we shall furnish it for $2.50 per bushel. In smaller quantites than a bushel, the price will be just double that of common buckwheat; viz., 70 cts. per peck, or 6 cts. per lb. If you want to see what it looks like, we will mail you a small package for 5 cts.

THE COMMERCIAL STANDING, OR RATING, OF BEE-KEEPERS AND SUPPLY-DEALERS.

I suppose the friends know that we have for years been in the habit of keeping a record of the business habits and financial responsibility of nearly every one who advertises extensively in our line of business. Furthermore, the Bradstreet Commercial Agency are in the habit of coming to us for information in this matter. As a matter of course, there are those who call us impertinent, and request us to attend to our own business; and we beg leave to say that we intend to make it our business to protect bee-keepers in every way in our power; and we do not see how we can serve them any more faithfully than to give warning promptly when we think the time has come to give notice that certain parties are not to be trusted. We shall, however, give due notice to the delinquent that we shall have to publish him if he does not make good his promises, and he will have ample time to straighten up or make arrangements before he is published, if he wishes to do so. Now, where disagreements and dissatisfaction come up between two parties, both known to be reliable, we do not care to have the matter referred to us; in fact, we have nothing to do with matters that seem to be only differences of opinion; but we do wish to be promptly notified when any one who advertises extensively does not keep his promises, or who receives money and does not make prompt shipments according to agreement. One reason why we like to be notified is, that we do not wish to continue the advertisement in our columns, of any man who is not able and willing to do all he agrees to do.

SLUG-SHOT FOR KILLING CABBAGE-WORMS, ETC.

In answer to many queries as to how to apply it, we reply: Take a piece of cheese-cloth, or any other thin fabric, say a foot or a foot and a half square. Pour about a teacupful of the slug-shot in the center of the piece of cloth, and catch the four corners up with your hand. Now walk through your cabbages, and with a quick jerk send a cloud of slug-shot down into the center of each plant or head of cabbage. We can not see that it makes any difference whether it is applied when the heads are damp or otherwise. Enough of the dust lodges on the foliage to kill the worms. So far as our experience goes it is sure death to them. With potato-beetles, however, it does not seem to be so certain in its results; neither have we been very well satisfied with the way it acts on the little black flea-beetles. Slug-shot is a poison, no doubt; but the poison is so diluted with some other substance that there is very little danger that any thing will be damaged or in any way injured for table use, even though the material be dusted on quite freely.

EGGS FRIED IN THE SOLAR WAX-EXTRACTOR; NO JOKE THIS TIME.

June 12.—To-day being unusually warm (85° in the shade) the thought occurred to me to try the solar wax-extractor. After going back of the factory, it was opened up and set in position in a twinkling. Very soon the thermometer indicated 235 degrees. I (Ernest) next went into the cook-room (an adjunct for convenience to the factory hands) and obtained an egg and a shallow tin pie-plate. In a moment more old Sol was smiling warmly upon the broken egg. After a lapse of 15 minutes the egg was nearly cooked. In 5 minutes more it looked tempting to a hungry stomach; but I am sorry to say I wasn't hungry just then. I left, and soon forgot all about it. When I returned in an hour afterward the egg was burned so as to be unfit to eat. For melting wax, the new solar wax-extractors are a grand success—no daubing, no soiled clothes, or wax-stained floors; and, best of all, your better half will rejoice with you. If you haven't any, and think you can't afford it, perhaps she will forego the pleasure of a new hat. The price of the solar wax-extractor we advertise is $3.00, all complete.

OUR TEN-CENT FIRE-BALLOONS.

ERNEST suggests that it is time for us to give them a notice; but I replied that I couldn't exactly see where they came in in bee culture. Perhaps we might mention them in the line of home interests. Huber has been teasing all the spring, "Papa, can't we send up a balloon?" I told him it was too windy. But finally, last evening, when he made his oft-repeated request, just about sundown, the weather seemed to be just the thing; in fact, the air was so still that the first balloon started almost straight up. When at a certain height a soft breeze wafted it to the eastward; 100 feet higher, another breeze started it northward, and a little higher still, a third current carried it to the west, so that when it came down it dropped not very far from the point of starting. About the time three or four had ascended, we had quite a picnic of all the children in the neighborhood, and they brought them back to be sent up over again as fast as I could put on new combustibles and scratch matches on the sidewalk where I sat, boss of the entertainment. Price of the balloons, 10 cts. each. If wanted by mail, 17 cts. each. Extra combustibles, 1 ct. each, or 10 cts. a dozen. If you want the balloon to go extra high, tie on two of the combustibles instead of one. Each balloon is furnished with one combustible.

AN ADJUSTABLE VEST-POCKET WRENCH FOR ONLY A DIME.

WHEN we succeeded in getting an adjustable wrench for 35 cts. we thought we had done a big thing, and so we did; but now one of the enterprising firms down East has actually got out a little wrench that we can retail for only ten cts., by buying them in lots of five or ten gross at a time. When shut up, the wrench measures just 4 inches in length. When the jaws are opened wide they will get hold of a nut one inch square, and from that down to nothing. In working on a farm, in a mill, or handling any kind of a machine put together with bolts, these little wrenches are invaluable. One day we were working out in the field with the cultivator. It needed a different adjustment; and just as I began to look cross on account of the delay in our work, Mr. Weed fished one of these out of his pocket, and began turning the nut. Said I, "Why, Mr. Weed, where in the world did you get that nice little wrench?"

He replied, "Mr. Root, I bought that for a dime from your ten-cent counter." And then I found out that John (John is the purchasing clerk now) had bought a lot of them, and put them on the counters before I even got around to look at them. I said right away that we wanted a "carload" of them and I think so still. That is, when all the friends all over the world find out how handy these wrenches are it will need a carload to supply the demands of the trade. Next month we will try to give you a picture. If wanted by mail, add 6 cts. each extra for postage.

A FOLDING YARD-STICK FOR ONLY 5 CTS., ONCE MORE.

THESE were taken out of our price list some time ago because we could not get them. We have now, however, not only the same thing, but something better still. While one side of the measure is graduated to inches and eighths of inches, the other side is graduated on the metrical system, being just one meter in length. Each fold is one-tenth of the meter, or a decimeter, just as a dime is one-tenth of a dollar. Then each decimeter is divided into tenths, or centimeters, just as a dime is divided into cents; and as a cent is the one-hundredth part of a dollar, so is a centimeter the hundredth part of a meter. Then each centimeter is divided into tenths; each division is called a millimeter, or thousandth of a meter, just as a dollar is divided into mills, or thousandths of a dollar. In short, the meter is divided into lengths, just as a dollar is divided into values. It is well worth 5 cts. to you, to see how the decimal system works. The meter is something more than a yard, being a little more than 39 inches, hence it bears no exact relation to a yard. The unit for the meter is made by taking the ten-millionth part of the earth's circumference lying between the equator and the north pole, the meridian running through Paris. The price of this wonderful measure is only 5 cts. If waited by mail, 2 cts. each extra for postage. Besides all of the above valuable qualities of this little implement, it is the nicest thing to give the baby you ever saw. He will fold it and unfold it, and keep playing with it for hours and hours; and every morning when he wakes up it will be just as new—at least for a time, unless your baby is more than ordinarily quick to detect old playthings.

TINNED WIRE NO. 30 ON A SPOOL HOLDING JUST ENOUGH FOR 100 FRAMES.

FOR the convenience of many friends, we have had our tinned wire put up in spools of the above size. The amount required is 10 ounces. Price of the same, 15 cts.; 10 spools, $1.25; 100, $12.00. If wanted by mail, add 12 cts. each extra.

KIND WORDS FROM OUR CUSTOMERS.

THE NEW WHEELBARROW.

The wheelbarrow and other goods arrived in good time. I am very much pleased with the same. The wheelbarrow is the nicest I ever saw.

Bernardsville, N. Y. WATSON ALLEN.

HOW OUR BEES GIVE SATISFACTION.

Those four cages of bees, each containing a queen, came to hand promptly, and in good shape. I received them Saturday evening and carried them eight miles in a buggy, through the rain. I kept them in the house till Monday forenoon, and then introduced them in hives full of combs and some honey, and in less than an hour the bees were all over the lawn, thick with dandelion blossoms, gathering honey and cleaning house, apparently as much pleased with their new home as a boy going fishing. I admire your prompt and straight way of doing business, for which you have my thanks.

Omer, Mich. S. B. SHRAUGER.

BEE-HIVES
—AND—
ITALIAN QUEENS

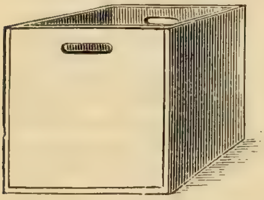
After June 15th, queens, $1.00; 6 for $5.00; 12 for $9.00. Bees by the pound, same as queens.

No. 1, all-in-one-piece sections, 4¼x4¼x1⅞, and 1¾, per 1000, $4.00; 10,000 for $37.50.

B. J. MILLER & CO.,
12-13d NAPPANEE, ELKHART CO., IND.

POTATO-BOXES

(TERRY'S).



These are made of basswood, bound with galvanized iron. The galvanized iron gives strength, and the basswood strength and lightness. These hold exactly a bushel when level full, and may be piled one on top of another. Although they are made especially for potatoes, they can be used for fruit, vegetables, picking up stones on the farm, and a thousand other purposes. When piled one above the other, they protect the contents from the sun and rain; and from their shape a great many more bushels can be set into a wagon than where baskets are used. They are also much more substantial than baskets.

Price 25 c each; 10, $2.25; 100, $20.00. In the flat, including nails and galvanized iron, $1.75 for 10; 100, $16.50; 1000, $150.

A. I. ROOT, MEDINA, OHIO.

CHEAP!

Full colonies in Simplicity hives, and honey enough to winter, for only $4.50. *Will ship, last of July.*

DAN WHITE,
11tfdb NEW LONDON, HURON CO., OHIO.

ITALIAN ❧ CARNIOLAN QUEENS.

Bred in separate apiaries, away from other bees. Warranted Italian or untested Carniolan queens, in May, $1.25; 6, $6.75; June, $1.10; 6, $5.90; July, $1; 6, $5. State which you prefer, Italians bred from my *Bellinzona strain*, or *Golden Italians*. I am prepared to please all.

BEES AT REDUCED RATES.

ALLEY'S DRONE AND QUEEN TRAP

Is the only one that has been tested for years and found to work perfectly. Other traps are an infringement on my patent. Sample trap, latest improved, by mail, 65c.

NOTICE.

Anybody can make and sell my traps by purchasing the brass stamps to be attached to each trap. Send for prices.

12-13 **HENRY ALLEY,** Wenham, Mass.

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

SECOND QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

These prices are good only when you take a full roll. If you order less than a roll we charge 7c. per sq. ft. Sometimes the roll you order is gone before your order reaches us, in which case we send the next largest roll, unless it is a great deal larger.

SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED.

This wire cloth is second quality. It will answer nicely for covering doors and windows, to keep out flies; for covering bee-hives and cages for shipping bees; making sieves for sifting seeds, etc.

Inches Wide.	No. of Rolls.	Number of Square Feet contained in each Roll Respectively.
36	70	22 rolls of 217, 37 of 216, 1 of 195, 2 of 215 s. f.
28	5	4 rolls of 233, and 1 of 234, s. f.
24	2	2 rolls of 281 s f.
38	37	26 rolls of 316, 2 of 317, 1 each of 632, and 285 s. f.
24	1	1 roll of 245 s. f.
44	2	1 roll of 366, 1 of 348 s. f.
48	1	1 rolls of 400 s. f.

FIRST QUALITY WIRE CLOTH AT 1¾ CTS. PER SQUARE FT.

The following is first quality, and is worth 1¾ cts. per square foot. It can be used for any purpose for which wire cloth is ordinarily used; and even at 1¾ cts. per sq. ft. it is far below the prices usually charged at hardware and furnishing stores, as you will ascertain by making inquiry. We were able to secure this very low price by buying a quantity of over one thousand dollars' worth.

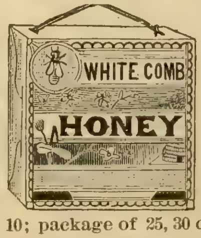
Inches Wide.	
24	40 rolls of 200 sq. ft. each.
26	56 rolls of 216 sq. ft. each; 1 each of 199, 195, 201, 200, 227, 204 sq. ft.
28	72 rolls of 233, 10 of 224, 6 of 222 sq. ft.; 1 each of 257 sq. ft.
30	36 rolls of 250 sq. ft.; 1 of 275, square ft.
32	13 of 266, 7 of 256, 1 of 253 sq. ft.; 1 of 275 sq. ft.
34	30 rolls of 283 sq. ft. each.
36	22 rolls of 300 sq. ft. each; 1 each of 288, 279, and 285 square ft.
38	1 roll each of 300 and 316 sq. ft.
40	1 roll of 233 square feet.
42	1 roll of 350 square feet.
46	1 roll of 192 square feet.

A. I. ROOT, Medina, Ohio.

PASTEBOARD BOXES

FOR ONE-POUND SECTIONS OF

COMB HONEY.



This box has a bit of "red tape" attached to it to carry it by. It makes a safe package for a single section of honey for the consumer to carry, or it can be packed in a trunk, if he wants. It can be opened in an instant. The price of the box is 2 cts. each, set up; in the flat, 15 cts. for 10; package of 25, 30 cts.; $1.00 per 100; or $9.00 per 1000; 10,000, $80. If wanted by mail, add $1.00 per hundred for postage. Colored lithograph labels for putting on the sides, two kinds, one for each side, $3.00 per 1000. A package of 25, labeled on both sides, as above, 50 cts. By mail, 30 cts. more. They can be sold, labeled on one side or both sides, of course. We have only one size in stock, for Simplicity sections. Sample by mail, with a label on each side, 5 cts. If you want them shipped in the flat, labels already pasted on, the price will be ten cents per hundred for putting them on.

Your name and address, and the kind of honey, may be printed on these labels, the same as other labels. The charge for so doing will be 30 cts. per per 100; 250, 50 cts.; 500, 75 cts.; 1000, $1.00.

A. I. ROOT. Medina. O.

QUEENS.

I have them, bred from a best selected queen of Root's importation, 90 cts. each; 6 for $4.50. I can give all orders immediate attention, and ship by return mail. Send postal for dozen rates.

KIND WORDS.

U. S. DEPARTMENT OF AGRICULTURE,
DIVISION OF ENTOMOLOGY,
APICULTURAL STATION,
N. W. MCLAIN, *Agent in charge.*
Aurora, Ill., June 25, 1886.

Mr. A. I. Root, Medina, Ohio:—

DEAR SIR:—Please accept my thanks for the copy of GLEANINGS kindly sent to my address here, and for the kindly mention of my work and the favorable indorsement of the same, which you have been good enough to make. It is my intention to do my duty under my instructions, and to serve the bee-keeping industry to the extent of my ability. The aid and encouragement received from those in whose interest this Station was established is appreciated, and is of great service.

I remain very truly yours, N. W. MCLAIN.

ITALIAN & CARNIOLAN QUEENS.

Bred in separate apiaries, away from other bees. Warranted Italian or untested Carniolan queens, in May, $1.25; 6, $6.75; June, $1.10; 6, $5.90; July, $1; 6, $5. State which you prefer, Italians bred from my *Bellinzona strain*, or *Golden Italians*. I am prepared to please all.

BEES AT REDUCED RATES.

For full particulars, and prices of tested queens, bees, etc., send for circular and price list. Satisfaction guaranteed. **CHAS. D. DUVALL,**
9tfdb **Spencerville, Mont. Co., Md.**

SPECIAL OFFER.

After this date I will furnish untested queens for 75 cts. each, $4.00 per ½ doz., or $7.50 per doz. Tested, $1.50. Warranted queens at $1.00; 2-frame nuclei, with untested queen, at $2.00. Ref., A. I. Root.
Address A. B. JOHNSON,
12d Clarkton, Bladen Co., N. C.

WANTED.—A partner to take half-interest in an Apiary, with a little capital. Address
LOUIS WERNER, Edwardsville, Ill.

MY 18TH ANNUAL PRICE LIST OF ITALIAN, CYPRIAN, and HOLY-LAND BEES, QUEENS, NUCLEUS COLONIES, and APIARIAN SUPPLIES, sent to all who send me their name and address.
10 11tfd *H. H. BROWN, Light Street, Col. Co., Pa.*

HAVING moved my large queen-rearing apiary from Lewisville to Milton, I will still furnish pure Italian bees and Queens in any quantity and shape. Those wanting to start apiaries should write for prices. I also will furnish eggs from California bronze turkeys, at $1.50 per sitting of 9.
3-19d GEO. W. BAKER, Milton, Ind.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or $2.00 per annum, when given once a month, or $4.00 per year if given in *every* issue.

$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or $2.00 per year.

Those whose names appear below agree to furnish Italian queens for $1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for $1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

HONEY COLUMN.

CITY MARKETS.

CHICAGO.—*Honey.*—Very little good comb honey on the market. A few lots of new have come forward and sold at 15@16c per lb. Extracted unchanged. *Beeswax*, 25c. R. A. BURNETT,
June 22, 1886. 161 So. Water St., Chicago, Ill.

CINCINNATI.—*Honey.*—Demand for extracted honey has been very slow of late, but seems to be improving gradually for manufacturing purposes. There is much honey in the hands of commission merchants, and prices are very low in consequence thereof; 3½@7c per lb. is the range of prices on arrival. Prices of comb honey are nominal.

Beeswax.—Arrivals are good, and demand is fair. We pay 18@22c per lb. for fair to choice yellow.

CHAS. F. MUTH & SON,
S. E. Cor. Freeman and Central Avenues,
June 23, 1886. Cincinnati, Ohio.

ST. LOUIS.—*Honey.*—Receipts of new honey are becoming quite liberal, and the market somewhat depressed. Choice comb, 12½@14. Extracted in cans, choice, 8c; extracted in bbls., 5c for good.
June 23, 1886. W. T. ANDERSON & CO.,
104 N. 3d St., St. Louis, Mo.

CLEVELAND.—*Honey.*—The market continues very quiet; some new white clover has been received, and best 1-lb. sections are selling at 14c; old 1-lb., 13c; old 2-lbs., 10@11. Glassed sections are unsalable. Ext., 6@7c. *Beeswax*, 22c. A. C. KENDEL,
June 21, 1886. 115 Ontario St., Cleveland, Ohio.

KANSAS CITY.—*Honey.*—The honey market is bare of comb honey. The demand is very good, at fair prices. We have reports of a good yield everywhere. 1-lb. comb, 14@16c; 2-lb. comb, 12@13 for white clover. Dark, 1-lb., 10@12; 2-lb., dark, 9. Extracted, choice white clover and sage, 5@6 cents; dark, 3@3½, and no sale. *Beeswax*, 20@22. New white clover, in one and two pounds, begins to come in. CLEMONS, CLOON & CO.,
June 21, 1886. Cor. 4th & Walnut St's,
Kansas City, Mo.

BOSTON.—*Honey.*—No change in the price of honey. Sales slow. BLAKE & RIPLEY,
June 19, 1886. 57 Chatham St., Boston, Mass.

DETROIT.—*Honey.*—There is a little new comb honey in the market, and the best white is selling at 13c. The demand, however, is limited. *Beeswax*, prime at 25c. M. H. HUNT,
June 21, 1886. Bell Branch, Mich.

FOR SALE.—1000 lbs. of new white-clover honey, 7c per lb. Ripe, and A No. 1 in quality.
J. B. MURRAY, Ada, Ohio.

FOR SALE.—New clover honey in kegs, at 8c per lb., kegs included; also in comb, stored in 1-lb. sections, a fine article, 16c per lb., put up in small cases.
O. H. TOWNSEND, Alamo, Kal. Co., Mich.

FOR SALE.—2000 lbs. white-clover honey in new 75-lb. tin cans. Delivered on board cars here. $5.00 per can, can included. Honey of this year's crop. Satisfaction guaranteed. N. MURRAY,
Ada, Hardin Co., Ohio.

HARD-TIME PRICES IN JULY.

Two-frame nuclei of Italian bees, with $1.00 queen, $2.00. If a larger nucleus is wanted, add 50 cts. for each additional frame. Full colony, in A. I. Root's Simplicity hive, $4.50. Pure Poland-China pigs for sale. My pigs are from prize-winning stock, and are second to none. No fancy prices asked. I will guarantee safe arrival and entire satisfaction on both bees and pigs. Address N. A. KNAPP,
13d Rochester, Lorain Co., Ohio.

WANTED.—Reliable local and traveling salesmen to sell Lubricating Oils. E. F. DIETERICHS, Cleveland, O. Inclose stamp for reply, and mention GLEANINGS.

IF you want fine honey-gatherers, try J. P. Moore's strain of Italians. See "ad."

CARNIOLAN ✻ QUEENS.
Carniolans are the Gentlest Bees Known,
AND EQUAL TO ANY OTHER RACE FOR WORK.
THE QUEENS ARE THE MOST PROLIFIC.
I offer daughters, of Imported Benton Carniolan queen, raised in my apiary of 40 colonies of pure Carniolan bees, during the remainder of this season, $1 00 each; six, $5.00.
DR. S. W. MORRISON,
Oxford, Chester Co., Pa.

For Sale. COLONIES, NUCLEI, and QUEENS, AT LOWEST PRICES.
11-16db GEO. D. RAUDENBUSH, READING, PA.

Red-Clover Italians.
For the past month, Moore's Italians have been roaring away on a large field of red clover. Reduced prices: Warranted queens, each, 80 cts.; per half doz., $4.50. Safe arrival and satisfaction guaranteed. See ad. in June 1st number. Circular, giving full particulars, free. J. P. MOORE,
13d Morgan, Pendleton Co., Ky.

NOW READY, ITALIAN QUEENS.
1 queen, $1.00; 2, $1.80; 3, $2.50; 5, $3.75. Bees by the pound, nucleus, and colony. 13-15db
L. T. HOPKINS, Conway, Franklin Co., Mass.

I WILL ship full colonies of Italian bees during July, August, and Sept., in Simplicity hives, with a wire-cloth cover and bottom, combs straight, bees in good condition, for $4.25. Hybrids in same hives and in same condition, and No. 1 honey-gatherers, also gather honey from red clover, $4.00. Reason for selling so cheap is, I have too much work to tend to so large a lot of bees. I guarantee safe arrival by express. H. M. MOYER,
13d Hill Church, Berks Co., Pa.

QUEENS. I have 50 dollar queens laying now; can ship by return mail sure.
13d L. HEINE, Bellmore, Queens Co., N. Y.

LOOK HERE, BEE-KEEPERS.
COMB FOUNDATION. Wax worked into Vandervort fdn. on shares, or by the pound, at 12½ and 15 cts. per lb. Brood fdn., 43 cts. per lb.; surplus, 50 cts. per lb. Also strawberry-plants, the best of varieties, at $1.00 per 100. Orders filled promptly. C. H. McFADDIN,
13d *Box 35.* Clarksburg, Moniteau Co., Mo.

UNTESTED ITALIAN QUEENS, reared under swarming impulse, $1.00 each; 3 for $2.50; 6 for $4.50. Tested, $1.50 each. Safe arrival guaranteed. F. S. McCLELLAND,
13d Box 379, New Brighton, Beaver Co., Pa.

KENTUCKY QUEENS. Italians, Holy-Land, and Albinos. Tested, $2.00; untested, $1.00 each. Bees, 75c per pound after 15th July. PELHAM & WILLIAMS,
13-16db Maysville, Ky.

A. J. KING'S New Circular of CARNIOLAN, SYRIAN, and ITALIAN QUEENS, etc., will be *SENT FREE* on application. Address
13tfdb A. J. KING, 51 Barclay St., New York.

FLORIDA PALMETTO FANS,
By mail, postpaid, 75 cts. Send money by registered mail. W. H. STEACY, BOX 20, THONOTOSASSA, FLA. 13-14d

ITALIAN BEES IN IOWA.
60c to 85c per lb. Queens, 30c to $1.75, according to kind and time. Also bee-supplies and honey. Order from free circular. "How to Raise Comb Honey," an illustrated pamphlet, just out, price 5 cents. Address OLIVER FOSTER,
13tfdb Mt. Vernon, Linn Co., Iowa.

CHEAP!
Full colonies in Simplicity hives, and honey enough to winter, for only $4.50. *Will ship last of July.* DAN WHITE,
11tfdb NEW LONDON, HURON CO., OHIO.

GLEANINGS IN BEE CULTURE.
DEVOTED·TO·BEES·HONEY·&·HOME·INTERESTS.
F.A.Whiting

Vol. XIV. JULY 1, 1886. No. 13.

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00; 10 or more, 75 cts. each. Single Number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent TO ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

NOTES FROM THE BANNER APIARY.

No. 79.

CLEANING HONEY-BOARDS.

As I have mentioned before, the only objection that I have to the wooden queen-excluding honey-boards is, that the bees fill the holes with propolis and wax. They are more inclined to do this when but little honey is being brought in. I have just been cleaning about 50 of them. I took a piece of hard wood, two inches wide, ¼ inch thick, and seven or eight inches long. One end of this was carefully planed down upon the sides until it was exactly 5-32 thick. This thin end was placed over an opening that was filled up, and the upper end given a light rap with a hammer, which clears the hole pretty effectually. To prevent the stick going through too far, a nail is driven through it half an inch from the lower end. The honey-board is supported by placing it upon two Heddon cases set upon the floor, perhaps four or five inches apart; but this operation did not free the holes so completely as I could wish, as there seemed to be a little wax adhering to the sides. To remove this, a ten-penny nail was fastened into a bit-stock, thrust into each opening, and turned slightly until the corners scraped the sides of the hole as it was passed from one end to the other of the slot. This cleaned them out completely. I have been making some honey-boards like Tinker's; that is, they are similar to the Heddon slat honey-board, except that the edges of the slats are grooved with a fine saw, and strips of perforated zinc slipped in between the slats. They cost a trifle less than an all-zinc board; have the desirable rigidity so necessary for keeping the bee-spaces exact, and I no not *think* the bees will fill the holes any more than they would in an all-zinc board.

SWARMING-OUT MANIA.

I have never had bees "act so" about staying in their hives after being hived, as this season. I do not know to what to attribute it, unless it be the light flow of honey that characterized the fore part of the season. Don't say it was because they didn't like the new Heddon hive, as all were not hived in that; in fact, the two swarms that gave the most trouble (one coming out four and the other five times) were hived in the old style of Heddon hive. I thought it might be caused by contracted brood-chambers, until two swarms re-swarmed that did not even *fill* the brood-chamber—swarms that had no business to have swarmed in the first place, as they were not strong enough, and swarmed, I suppose, simply because their neighbors did. As the honey-flow improved, so did the behavior of the bees; still, an occasional swarm "acts up." After we had lost three swarms by their "going west" (every one went *west*), preconceived notions were tossed to the winds, and we fell to

CLIPPING THE QUEENS' WINGS.

The first swarm came out and left early in the season—so early that we didn't expect it. It kindly came up past the house, though, to say "good-by," but too high above us to "shake hands." The second swarm left in spite of the combined efforts of two whole families. Brother and I followed it about a mile, and our wives and the twins followed us, or *tried* to follow us, with pails of water; and when we returned, tired, hot, disgusted, chagrined, and *unsuccessful*, it was decided, by *vote*, that every queen should have her wing clipped. These $5.00 arguments in favor of clipping were becoming too numerous. But we finally reconsidered, and decided to wait until the bees swarmed, and *then* find the queen, and clip their wings, which we have done. So expert have we become in catching queens that we catch most of them as they leave the hive. A queen seldom takes wing the moment she reaches the entrance of the hive, but usually drops on the ground about a foot in front of the hive, remains there from one to five seconds, then slowly rises and flies. We have sometimes caught them in our hands after they had risen to fly. If the queen is not found as the swarm is issuing, the swarm is shaken into a basket, the edge of the basket placed at the entrance of the hive, when the bees will begin to crawl in and to *spread out* over the inside of the basket. As the basket is lined with white cloth there is not much difficulty in finding the queen. One of us is in the apiary from between seven and eight in the morning until between four and five in the afternoon, yet one colony cast a swarm when we didn't know it, and we didn't discover it until it cast a second swarm, when the "brand-new" look of the queen aroused our suspicions, and investigations followed. I have never had more than 75 colonies, spring count; and with an apiary of that size, I should prefer not to have the queens clipped, if the bees would stay hived, and they usually have until this season; but in a large apiary it has always seemed to me as though several swarms issuing at once would give much trouble unless the queens were clipped. The best remedy that I can suggest would be to have several small tents scattered about the yard; and if a swarm is *seen* at the *outset*, set a tent over it until the swarm in the air is cared for. We have used our tent in that way several times this season, and it works like a charm.

REVERSAL PREVENTING SWARMING.

None of our colonies that we have been practicing reversing upon have yet swarmed; but as the number is limited, and they may yet swarm, I do not consider it a fair test, and I mention it only that others who are trying reversing may also notice in regard to the matter. At present I do not care to prevent the issuing of *first* swarms; but many bee-keepers would be glad to know that inverting a hive once a week would prevent its occupants from swarming.

W. Z. HUTCHINSON.

Rogersville, Mich., June, 1886.

You will notice, friend H., that friend Alley, on another page, strikes on the point you mention; viz., that reversing the brood-chamber will have a tendency to prevent swarming. This is quite an important matter, and we shall be glad to have reports from those who have tested it to see. I believe it is true, that many colonies are induced to swarm because they hear their neighbors swarming; and this sometimes gets to be quite a serious trouble, especially where the owner of the apiary wishes to secure comb honey. I believe most of our veterans own up defeated at such times. Friend Hasty, you will remember, during one season could discover no other way to cure the swarming than to bury the truants for two or three days in the ground.

EMPTY FRAMES, EMPTY COMBS, OR FOUNDATION?

FRIEND HUTCHINSON TELLS US WHICH, UNDER CERTAIN CIRCUMSTANCES, AND GIVES THE WHYS AND WHEREFORES.

IN the *Canadian Bee Journal* for May 26, p. 169, occurs the following query:

> In the honey season, if I had three first swarms come off within a few minutes of each other, and I were to put one in an empty hive, another in a hive filled with foundation, and the third filled with worker-combs, each swarm weighing 6 lbs., how much extracted honey would each yield in the first ten days? W. M.

We have not space for the answers to this query; but friend W. Z. Hutchinson writes so valuable an article in regard to the matter, on page 249 of the *C. B. J.* for June 23, that we give place to it below:

I was much interested in query No. 75, asking which swarm would store the most extracted honey the first ten days after hiving, one hived in an empty hive, one given foundation, or one given empty combs.

I wish that the query had been put in a little different form. Modern apiculture has divided a beehive into two radically different apartments—brood-nest and surplus-department. Of course, the brood-nest *can* be made so large as to allow room for the honey as well as the brood; but most apiarists now prefer to have the brood by itself, and the honey by itself. In view of this I should like to put the query something like this: If the *brood-chamber* of one hive is furnished with foundation, another with empty combs, and a third with empty frames, swarms exactly alike are hived at the same time in these hives, while the *surplus* apartments are furnished with foundation, or empty combs, which surplus-apartment will contain the most honey (either comb or extracted) at the expiration of ten days, or at the end of the season, and which brood-nest will contain the most brood? The bees are to be given access to the surplus at the time of hiving, and the brood-chamber must be of such a size that the bees must, of necessity, also occupy the surplus-apartment. Unless empty combs are used, a queen-excluding honey-board will be needed.

According to experiments which I have made during the past two years, the swarm that builds its combs in the brood-nest will store the most honey in the surplus-apartment, and have the most brood in the brood-nest; next will come the swarm given foundation, while the swarm with empty combs will put the least honey in the super and rear the least brood. The experiments that I have made consisted of hiving one swarm on empty combs, the next on empty frames, and the third on foundation, continuing in this way until about 40 swarms had been hived each year.

When combs are given, the bees proceed at once to fill them with honey, which in good honey weather they will often do in two days. In this way they get the start of the queens, and they *keep* it. I can not tell why it is; perhaps the bees feel that their job is finished; but after filling a set of combs in the brood-nest, bees are very reluctant to commence in the boxes. Where they store their first honey after being hived, there they seem willing to continue to store it; and when foundation is given in the brood-nest, and *combs* in the surplus-apartment, the first honey goes into the super, as no honey can be stored in the brood-nest until the foundation is drawn; but in two days, foundation becomes *comb*, and then the bees will store considerable honey in the brood-nest; but they will continue to work in the supers, as they have made a *start* there. When hived upon empty frames, and given combs or foundation in the super, all the honey must be stored in the super until combs can be built in the brood-nest; and just as soon as a few cells are started in the brood-nest, the queen is ready to fill them with eggs; and as soon as the eggs are laid in a comb that is being built, the storing of honey ceases in *that* comb, as no honey is stored below where brood is started. The queen can keep pace with the building of natural comb, but *not* with the drawing-out of foundation When a swarm is hived upon empty frames, and given access at once to a super, furnished with foundation or combs, the result is that all the honey goes into the super, while the brood-nest is filled with sheets of solid brood. According to the experiments that I made, if the foundation had been given to me it would have been used at a loss when put into the brood-chamber and swarms hived upon it.

At the Detroit convention, Mr. H. R. Boardman said he had tried hiving swarms upon empty frames, and was pleased with the result. Mr. J. B. Hall had also tried it, but too much drone comb was the result. This I attribute to his large brood-chambers.

Mr. Doolittle's article, "Production of Wax," is right to the point. Because bees in confinement require twenty pounds of honey to produce one pound of wax, it does not follow that a new swarm can not build the combs in the brood-nest to better advantage to their owner than to draw out foundation.

Mr. Doolittle speaks of dispensing with foundation because it is expensive. "A penny saved is a penny earned," etc. That is not the question. Bee-keepers do not look upon foundation as a *luxury*—something that *could* be dispensed with—but rather a *necessity*. It does not pay to "retrench as much as possible" in the use of *some* things. The question is, "Does it pay to use foundation in the brood-nest when hiving swarms?" If it *does*, where is the economy of allowing bees to build their own combs? If it *pays*, the more we use the larger the profit; and if it *doesn't*, nobody will be fool enough to use it simply for the fun of the thing.

Rogersville, Mich. W. Z. HUTCHINSON.

After reading the above, a great many things not heretofore plain became all at once easy to understand. For instance: Just before we commenced manufacturing extractors, a neighbor brought me a good-sized swarm of black bees. I had been buying all the bees in the country around, and at prices that enabled our country friends to take a horse and buggy and bring me every swarm as fast as it came off. Well, the swarm mentioned was brought about the middle of July, the owner expecting I would give at least $5.00 for it. I told him the basswood yield was so near over I could not possibly give over $2.00; and some of my old bee-friends thought the bees were not worth any thing, because they could not possibly gather honey enough to winter. I had my own ideas in regard to it, however. I gave the bees a full set of combs, and they went right to work, and in two days their combs were almost like lead, the honey sparkling from corner to corner — none of it capped over, of course. To my surprise, not an egg was to be seen, and I began wondering if they were not queenless. I gave them more room, however, but no eggs were found for something like a week. The honey came so fast that the queen didn't have a chance to commence, or perhaps the bees were so eager to improve the time that they couldn't stop to prepare cells for her use. Now, then, friends, had the empty combs I gave the bees been shallow, say four or five inches deep, and had room been provided below for comb-building, the honey would all have gone into these shallow combs. New combs would meanwhile have been built under them, which the queen would have occupied with brood. Thus we see how plain it is that more *honey* will be stored in the sections where the new swarm is given empty frames than if they had empty combs, or even frames filled with foundation. We should be very glad of more experiments on this subject while the season permits.

Of course, this condition of affairs refers to comb honey. Where one is working for extracted honey, by all means give them empty combs; and if you can not do that, give them empty frames filled with foundation. New swarms will give enormous quantities of extracted honey, if provided with empty combs when first hived; that is, if I am correct in the matter; and I should be very glad indeed to have friend Hutchinson's opinion in regard to this latter — that is, if he has ever tried working new swarms for extracted honey.

INDUCING BEES TO COMMENCE WORK IN THE SECTIONS, ETC.

GLEANINGS AS AN ADVERTISING MEDIUM.

THAT GLEANINGS is a first-class medium for advertising, has been fully proved to myself, while at the same time it has added largely to my labors in the way of answering letters. A few weeks ago, it may be remembered, I gave a method of my own for enticing or forcing bees into sections, by shaving combs in the brood-chamber to ⅞ inch thick, spacing them just a bee-space apart, and putting on sections at the first approach of the honey season. Well, for the last three weeks letters have been coming to me from various sections in regard to the matter; and, strange to say, every one from persons who had tested, in a small way, the method I described; but it is not at all strange that every one had found the method did work just as I had stated it would. One writer is very enthusiastic over it, saying that, with him, it does a thing that has bothered him for years, and is the only reasonable and easy way of getting bees into sections that he has ever tried. And with myself, I desire to say that it works every time; there are no failures, and there can be none, as it is in direct accordance with the natural habits of the bees, and is only doing with frames just what they do in box hives and hollow trees. It is useless to expect that a frame hive alone, no matter whose patent it may be, will give us good results, without *some* labor on our part. The point is, to do the required labor in the easiest, cheapest, and most natural way, because this will be found the best way. I trust that every one who has written to me will report the results in GLEANINGS and the other journals, so that, if the plan is of any value, the fraternity may all know it, and have the benefit of it. As it can be tested at any time, and with any hive, it will cause no trouble to do so, and the results, I know, will be surprising to any who are at all skeptical.

INTRODUCING QUEENS.

It seems a little strange to me that so many find trouble in introducing queens. I admit, that I once found great trouble myself; but the most of it was caused by over-anxiety. The so-called "Simmins method" is so nearly absolutely safe, however, that the veriest novice would not lose 2 per cent by using it, while the expert will meet with comparatively no loss at all; and if he should, it would be one of those cases where the loss was unavoidable, and would have happened under any circumstances. I use, however, a modification of the "Simmins method," and deem it fully as simple and handy. I have introduced many queens by my way, and never lost one yet. Some of these queens were virgins, but almost all were fertilized. The plan or method I use altogether now is, to remove the old queen, just after the noon hour on a bright day, when the bees are flying briskly. At dusk of the same day, and after the flying for the day has ceased, I give the colony a little smoke, wait three or four minutes for the bees to fill themselves with nectar, and then let the new queen run directly in at the entrance. I do not open the hive, or trouble it at all for four or five days after the introduction. I have no faith or belief in the "scent" theory; but if any do, they might keep the new queen caged on top the frames for a day or two; but to introduce safely, the new queen must be allowed to enter the hive on the same day the old one is removed, and the hive must not be opened for three or four days. I have not found that it made any difference whether honey was being gathered freely or not; but as possibly this may be owing to the fact that I always feed a little when no honey is being gathered from the fields, it may be advisable, if the attempt to introduce is made during a honey-dearth, to feed enough to keep a colony on its good behavior. I should never attempt to introduce a queen on the day she came from a distance, in any case, but should allow her to remain for a day or two on the frames of some hive, in order that she might get rested from the effects of the journey, and her ovaries be stimulated to their accustomed vigor; and this might as well be done on the frames of the hive she was to be given, as on any other. I have formed a theory in regard to this matter of introducing, but will not give it here, as space just now should be devoted to fact, and not given to theories.

Foxboro, Mass., June 15, 1886. J. E. POND, JR.

Friend P., your suggestion in regard to getting bees in sections is certainly an important matter. I suppose that this operaation of shaving combs to $\frac{7}{8}$ inch uncaps the greater part of the unsealed honey along near the top-bar. Some years ago a correspondent stated that uncapping the sealed honey would cause the bees to move a part into the sections. Moving the combs up near together, probably still further tends to secure the result. We have practiced your method of introducing queens, quite extensively; and there are so few failures, I think we can often afford to lose a queen once in a while, rather than to take the time required by other methods.

MAILING QUEEN-BEES WITHOUT ATTENDANT WORKERS.

A NEW RULING OF THE U. S. POSTOFFICE DEPARTMENT IN THE MATTER.

SINCE what we wrote on page 537, the following has come to hand from Prof. Cook:

Dear Mr. Root:—I have conferred with our President, ex-Congressman Willits, and he suggests that we send a great number of petitions to Hon. John Jameson, General Superintendent P. O. Department, stating the fact that queens can not be shipped without attendants, and urging that the ruling be changed. I will ask Mr. Newman to act at once through the Union. You had better also push the matter, through your subscribers. Mr. Willits will write to Jameson personally; as he knows him well, his appeal will have great weight.

The Canadian matter is a matter of treaty, and we can not easily cure the evil, if we can at all. I can not go to Washington before winter, when, if it seems wise and best, I can go. A. J. COOK.

Agricultural College, Mich., June 23, 1886.

Now, friends, you see what we have to do. It looks as if it were a move somewhat similar to the one relative to increasing the postage on seeds and merchandise. It hardly seems possible that the postoffice department should for a moment think of trifling with a matter concerning our great and growing industry; and to make a ruling that live queen-bees could pass in the mails without the half-dozen attendant workers, is surely a blunder, and not intentional. We hope the proper officials will make haste to right the great wrong they have come so near doing. Meanwhile, let us make ourselves heard. Will every bee-keeper follow friend Cook's advice, and send in his petition to his Congressman?

HUMBUGS AND SWINDLES

PERTAINING TO BEE CULTURE.

We respectfully solicit the aid of our friends in conducting this department, and would consider it a favor to have them send us all circulars that have a deceptive appearance. The greatest care will be at all times maintained to prevent injustice being done any one.

THE GOLDEN BEE-HIVE.

I NOTICE a caution from *Agriculture Wheel*, No. 383, Independence County, Ark., notifying the Wheelers to be aware of the agents of the Golden bee-hive. They say it is a humbug and a fraud, and gave reference to you for their authority. Now, as their agents are in this section, selling farm-rights at ten dollars each, I wish you to inform me of the facts, and in what particular. Is it because they sell a patent-right and have none, or is it because it falls short of its recommendation and representations? D. D. BREWER.

Springfield, Conway Co., Ark., June 14, 1886.

Friend B., I am not able to say whether there is a valid patent on the Golden beehive or not; all I can say is this: That the men who have for years been traveling about selling rights for the Golden bee-hive have been, every little while, published on account of their swindling operations; and if the parties you speak of are selling farm-rights for ten dollars each, I should say they belong to the same class. They and the people who buy of them are behind the times. Successful modern bee culture requires no farm right or right of any kind; and the money that is obtained is, almost invariably, obtained by making false pretenses. Investigation usually shows that the features claimed by the men selling rights are common property, and have been for years.

F. E. FROSS AND HIS STUMP-BURNING PENETRATIVE.

We clip the following from the *Farm and Fireside:*

The U. S. postal authorities recently arrested the propagandists of the wonderful "Acme Penetrative," for burning stumps, whose headquarters of late have been at New Carlisle, Ohio, the charge being that of using the mails for fraudulent purposes.

THE FIRM OF JANE MEEK & BROTHER.

A Serial Story in Ten Chapters.

BY REV. W. D. RALSTON.

CHAPTER VII.

THE BUSY SEASON.

AT length the eighth day from the one on which the first swarm issued arrived; but it was a dark, rainy day, and of course no swarm was expected that day. In the evening the children called their father and mother out to listen to the queens piping. When Mr. Meek had listened for a few moments he said, "You may expect a swarm to-morrow, if it is a fair day," and he was not mistaken. This swarm surprised the children by clustering on the very spot on which the first swarm had clustered. Their father explained that such was often the case; that, in large apiaries, frequently swarm after swarm would cluster on the same limb; that probably there was a scent left that attracted the next swarm.

The children were not so wild with excitement as on the former occasion. They put on their bee-hats and hived it themselves; their father looked on and gave some directions. The bees were marching into the new hive nicely, and the children were watching them intently, hoping to see the queen, when Tommy suddenly began to dance on one foot, as though greatly pleased. He did not clap his hands, crying, "Good, good!" but grasped his pants behind the right knee with both hands, and cried, "Crackee! crackee!" His father asked what was wrong, when he cried out, as though in great pain, "I am stung, I am stung! oh dear! oh dear!"

Jane's arm was soon around his neck, and comforting words were whispered in his ear. She said, "Poor little Tommy! how I pity you! but you know we are bee-keepers, and will both have to take some stings. We must just bear them as well as we can."

It seemed a bee had crawled up his pants on the inside, and inserted its sting under his knee, in a tender spot. His knee swelled considerably, making him quite lame; but his lameness lasted only that afternoon. His father told him how to prevent such an accident occurring again. If he had on boots he could tuck his pants inside; or if he wore shoes he could tuck them inside his socks, or else tie a string around the lower ends of the legs.

The bees in the nail-keg exhibited no disposition to cast a third swarm. The question with the children now was, what to do with the nail-keg hive. The old black weather-beaten nail-keg looked so badly alongside of the two nicely painted hives that they wished to get it out of the way. They read over what the book and papers said about transferring, and often talked it over with papa, but it was to all a thing they dreaded to attempt. Here a most fortunate thing occurred. Rev. Mr. Robb, an old friend and classmate of their father, came to pay him a visit. Mr. Robb had kept bees for years, and was expert at transferring, and readily agreed to undertake the job. As they desired increase, he said they could divide the colony and feed both up so they would winter. He first ordered from the supply-dealer a dollar queen and a dozen cheap feeders. A couple of empty nail-kegs were then procured; and just after dinner Mr. Robb removed the old hive, setting another nail-keg in its place, to retain the bees returning from the fields. After smoking the old hive he inverted it, and, placing the other empty nail-keg on top, closed all crevices by winding a sheet around where the two came together. He next drummed for some time on the lower keg with a stick. He then removed the upper keg, where nearly all the bees were found clustered in the top of it. He next cut away the hoops from the old hive and took it to pieces, taking out comb after comb which he fitted as well as he could into empty frames from the new hives, fastening them in with slender willow rods, tied above and below the frames. These frames of comb he hung in two empty hives. He was careful to fasten in all the brood he found, and also all the comb, except a few fragments. He then placed one of these hives upon the old stand, and the other upon a new one. The bees that had been driven out of the hive into a nail-keg, and kept covered up, were now brought, and a part emptied in front of the hive placed on the old stand; but the greater part were emptied in front of the hive on the new stand, and made to enter it as though they had just swarmed.

Mr. Robb explained to the children, that many bees would probably return to the old stand, and therefore he gave more to the one on the new stand. After contracting the entrances to exclude robbers, they were left until the new queen arrived. Mr. Robb then opened both hives and looked closely over the combs. In the one on the old stand he found queen-cells started, while he saw none in the one on the new stand, but found the queen upon one of its combs. He placed the new queen in the queenless hive, leaving her caged for thirty-six hours, and then, cutting out all queen-cells, released her, and she was accepted by the bees. Before he finished his visit he assured the children that his work had been a perfect success, and that they had a start of two good colonies; but that, whenever there was a dearth of honey, they must feed them sugar syrup, and he showed how the new feeders could be set inside the hive, alongside of the combs, which did not more than half fill the brood-chamber.

Frequent examinations convinced Mr. Meek that the first swarm would fill the case of sections placed upon it, and that the second swarm would about fill its brood-chamber, and that the two colonies made by Mr. Robb would need considerable feeding to prepare them for winter. After a time Mr. Meek told the children to prepare a second case of sections as they had the first. The case on the first swarm was raised up, and this empty case put in its place, and it was then placed on the top of the empty one. As the sections had not closed tops, the bees could work up through the empty one. To place this case on the hive required the entire family. Mr. Meek raised the whole case, and held it while Tommy slipped in the empty one. Jane, smoker in hand, kept the bees in subjection, while mamma gazed in admiration at the daring achievement. Here arose a difficulty. The cap was too small to cover two cases and reach its resting-place. Mr. Meek took a fence-board, and cut and nailed up a rim that filled up the vacancy nicely. As soon as the outside sections were sealed, the upper tier of sections was removed, but the second was left until the frost came.

When this new honey was taken and placed in the store-room, the whole family praised it highly. And when the honey was cut from a section into a dish, and placed upon their supper-table, they pronounced it delicious. Jane said, "It is better than any candy I ever tasted;" and Tommy added, "I tell you, our bees make the boss honey; the comb melts in my mouth. You remember, pa, the honey Mr. Baker sent us, how tough the comb was; you could hardly cut it, and it did for chewing-gum."

His father said, "Comb is never good to eat after bees have hatched in it. Each young bee opens a web around the inside of the cell. This makes the comb tough. As each bee hatched in the cell adds another web, old combs become very tough. This comb had no bees hatched in it, while Mr. Baker's had; hence the difference."

When the other case of sections was removed, after the first frost, it was found that there was honey in every section. Six in the middle were about finished, the rest only partly sealed, but could all be used in the family. In fact, it had already been decided that no honey should be sold that year. Their entire honey-crop was fifty-three pounds.

One evening, after supper, Jane produced the account-book of the firm, which showed as follows:

ARTICLES PURCHASED BY THE FIRM OF JANE MEEK & BROTHER.

Number of packages of sugar for feeding	$2.75
Five Langstroth hives	8.00
Five hundred sections	3 50
Freight on sections	.30
A box containing one smoker	.50
Fifty tin separators	1.50
Eight pounds of thin comb foundation	4.00
Freight on this box	.25
One dozen feeders	.60
One queen	1.00
	$22.40

Of this amount, $2.30 was from the children's pocket-money. The rest, $20.10, was money loaned the firm by Mr. Meek.

Of course, more supplies had been purchased than were needed, because these had to be shipped, and could not well be shipped in smaller lots than they had ordered, and they knew that any supplies left over would do for next season. The children made out the following account, to be placed opposite the expenses:

Supplies and utensils on hand	$9 60
Four colonies at $5.00 a colony	20.00
53 pounds of honey, at 15 cts. a lb	7.95
	$37.55

A comparison shows that, although the firm was in debt, there was a gain during the year.

Tommy did not like to be in debt, and said to his father, "You gave me a book about Benjamin Franklin, and told me to follow its teachings. You showed me what he said about debt, and said when I went into business to remember his advice, if I would be successful—to have as my motto, 'Owe no man any thing.' Now, our firm is deeply in debt. Are we doing right?"

His father answered, "If you had borrowed this money from a stranger, I would not approve of it; but as it is, I think it all right. You remember I gave my consent to you and Jane keeping bees for certain reasons. You are being educated. The money is invested in educating you to do business; to understand bees, and also to keep bees; and if the firm fails to pay me, I will not consider the money lost. This debt to me is not like another debt; I merely ask you to pay if able; and if disaster overtakes you, I wi'l forgive you the debt. An old farmer advised his son never to go in debt at all; 'but,' said he, 'if you do go in debt, let it be for manure.' I would say to bee-keepers, never go in debt at all; but if you do go in debt, let it be for improvements which will increase your yield of honey.

To be continued Aug. 1.

THE DOOLITTLE SURPLUS ARRANGEMENT.

CAN HONEY BE SENT TO MARKET IN THE SAME CASE IT COMES FROM THE HIVE?

IN your remarks on the Doolittle surplus arrangement for comb honey, in GLEANINGS, June 1st, you say: "Such an arrangement works nicely on hives, but is not practicable to use for shipping honey to market. For home use, however, it seems to answer every purpose." If I understand your last sentence, you wish to imply that the case is not practicable for bee-keepers raising honey for market, but only for those who raise honey for home use, etc. I should like to have you tell us if you ever sent comb honey to market in the cases in which it is built, in a marketable condition? Is the combined shipping and honey crate a marketable honey-case? For my part I don't think it is, and I don't think it is ever used for that purpose. The fact is, I don't know of any bee-keeper who ever sent his comb honey in the case it was built in. This arrangement that you call the Viallon plan, etc., instead of the Doolittle surplus arrangement, etc., has been used for nearly ten years by Doolittle, and it is from a sample arrangement of wide frames he sent you in 1876 that you came out and advertised the wide frames to hold eight sections, and your three-box case you say is similar, and advertised by you several years. I claimed no novelty in the arrangement; but as I used it with better results than any other case, and as it had not been made public, to my knowledge, before I saw friend Doolittle's article in the *A. B. J.*, I wrote to him and asked him permission to manufacture it and call it his arrangement, which is nothing but right, as he was the first one to use such an arrangement. I will take this opportunity to ask friend Doolittle to give us his views on the subject, in GLEANINGS. P. L. VIALLON.

Bayou Goula, La., June 12, 1886.

Excuse me, friend V., if I did not say just what I meant to say in my foot-note to your communication in our issue of June 1st. The combined shipping and honey crate illustrated in our price list has been used quite extensively about here, and I think generally in different localities, for taking honey to neighboring stores and groceries. It can be lifted directly from the hive; and after the bees have been expelled it is ready to be handed over to the grocer without removing a section, unless you think best to take out one or two, so he won't have any trouble in getting them started. As to whether it has been used for shipping on the cars or not, I do not know. I am inclined to think it has, however, because one or two complaints have been made that there is no ready method of closing the openings in the bottom, where the bees get in, during shipment. It is true, I first got the idea of tin separators from friend Doolittle; but he told me at once that they were not original with him—that he first saw them at his neighbor Betsinger's. We afterward found out that they were used and patented by another York-State man whose name I do not now remember, even before Mr. Betsinger used them. For the sake of economy, and to enable us to handle them as we handle a brood-frame, I suggested the wide frame, now in general use almost the world over. I certainly did not intend to omit giving credit anywhere; but most of these things have come up so gradually, and so many have contributed a little here and a little there, that it seems a pretty hard matter to call any of these things after the name of the inventor, unless, indeed, we do as our English friends do, and attach a string of names to something in common use that has been given us by quite a number of different people. As we do not produce comb honey, we are hardly prepared to decide which arrangement is best, all things considered. We manufacture whatever the brethren call for.

SOME SUGGESTIONS IN REGARD TO RETURNING SWARMS.

MY WAY.

IT is often necessary to return swarms of bees to the hive from which they have issued, when but little increase in the *number* of *colonies* is desired. My plan for doing this is to remove the queen or queens from the swarm, and thus compel the bees to go back themselves. Get the swarm into a shallow swarming-box, and carry them about 200 feet from the place where they clustered, and from the apiary. Gently shake the bees on to a sheet or wide board, and place the box two or three feet from them, so that the queen can be more easily found. She will often fly when the bees are shaken out, and will alight into or at the entrance to the box. If the queen should get into the box, and can not easily be caught, shake the bees out again, or carry the box with what bees are in it to a new spot, leaving those that are not in the box, thus having fewer bees to sort over.

As soon as the queens are taken away the bees will begin to get restless, crawling out of the box, and flying, and will soon return to the hive or hives from which they issued. If, after removing one queen, the bees should stay contented, they should be shaken out again, to find the other queens. If you do not care to save the queen, kill her by cutting with a knife-blade. This can be done without picking her up, which is quite difficult. I sometimes catch the queen in my hand when she is rising to fly. I like this plan of returning swarms better than cutting out queen-cells.

Removing and returning crates and supers to hives, mashing bees, looking over the combs for queen-cells, missing some that ought to be removed, taking the chances of leaving but one cell to hatch, and seeing the bees swarm after all, are more laborious and discouraging.

Should your choice imported queen swarm, and you do not see them issue, you will know it by the bees returning to their own hive.

A NEW INCUBATOR.

Would not some of the readers of GLEANINGS like to try the experiment of hatching chickens by the heat of a colony of bees? Now is the time to do it. Place a sheet of burlap on the frames, and a second story on the hive, then put loose chaff in the second story. Put in the eggs close enough to the bees to get the right temperature. Moisten and air the eggs occasionally. Should the bees swarm, return them. Will the eggs hatch? CHAS. A. WOOD, 20—23.

Tarrytown, N. Y.

I think, friend Wood, that the heat of a swarm of bees is not sufficient to hatch eggs. See what has been written in our back numbers in regard to the temperature of the brood-nest of a colony of bees. You will notice that it is not quite high enough for hatching eggs.

INTRODUCING VIRGIN QUEENS.

FRIEND LAKIN GIVES US SOME OF HIS EXPERIENCE IN REGARD TO THE MATTER.

SPEAKING of the lamp-nursery, the queens so hatched, and the methods of introducing such queens, you say: "It will be of no use to attempt introducing these queens by caging." Does this statement apply to all unfertile queens? Would there be, practically, any difference between a queen hatched in the nursery and one hatched in the natural manner? These are my reasons for the above interrogatories: May 29 one of my colonies cast a swarm—a second swarm, I had reason to believe; and after hiving the swarm, and satisfying myself that they were provided with a queen, I concluded I would remove the queen-cells from the old colony, to prevent a second or third swarm, intending to insert the choicest cells in some colonies I had unqueened. On examination I found seven young queens in the old colony, six of which were removed, caged, and introduced to as many queenless colonies. Having use for five queens myself, I gave friend Fisher the sixth. All were caged and successfully introduced to good strong colonies. One of my colonies I had unqueened the evening before the caged queen was placed in the hive. In this case the queen was placed in the colony, caged 24 hours. The remaining colonies were queenless from three to five days, as shown by the register. The cages were improvised—hurriedly and roughly made, yours not having arrived yet. The cages were placed over an abundance of uncapped honey, providing an abundance of stores for the queen. To-day the queens are all fertile, and apparently as prolific as any in the apiary. I have secured some of my choicest young queens by caging the cells, when within three or four days of hatching—unqueening where I wish to requeen, and placing the cage between the combs, being sure the cage is placed with the wire cloth over uncapped honey. Now, if queens can be so introduced; that is, by caging the cells in queenless colonies, there will be a wonderful saving in time over the method of giving unsealed brood and larvæ of the proper age for queen-rearing. Of course, cells can be given a queenless colony; but what is the percentage of losses by this method? With a caged cell they show evidence of a willingness to destroy the cell, but are unable to reach it. In six attempts at cell-caging, all have proven successful, and four queens so hatched are now laying queens; the fifth has the appearance and actions of a fertile queen; but when last examined, no positive evidence of her fertility was discernible. The sixth is too young to expect any thing from at this writing.

Now, Mr. Root, you know I am one of those little fellows; that is, I am in the A B C class, and the above may not be new or strange to you or your readers; but in view of your statement concerning the introduction of young queens by caging, I concluded I would write you concerning it.

Where can I find a description of friend Heddon's non-swarming method? S. W. LAKIN.

Eureka, Ill., June 12, 1886.

Friend L., this matter is by no means new. The whole thing has been gone over in our back journals. As a rule, virgin queens can not be introduced by caging, although at times there seem to be a good many exceptions to this rule. The most successful way of getting them into the colony is to let them loose among bees just as soon as they are hatched; and the success of the lamp-nursery depends upon this peculiar fact. Queens that come off with an after-swarm are in no way different from those hatched in the lamp-nursery; that is, providing they are introduced to the colony very soon after being hatched, as those in the lamp-nursery always should be. Your success is a little remarkable, although it is quite common to see bees accept of almost any thing you give when honey is coming in bountifully, as I suppose it was at the time of your experiments. Caging queen-cells has been discussed a good many times; but after a while the plan has been dropped. Friend Doolittle's plan, given in our last issue, may, however, bring it into general use. We have decided that as many, or more, cells are lost when giving the queenless colony a capped queen-cell than by giving them virgin queens newly hatched.—I should think you were having quite encouraging success, friend L., even if you are but a "little fellow" in bee-lore.—Heddon's plan of non-swarming is fully described in his new book, which we mail from this office on receipt of fifty cents.

FLORIDA AND ITS FLORA.

THE NATIVE BEES EXTREMELY LAZY.

SO much having been written in GLEANINGS about Florida, I thought I would try to enlighten some of the bee-keepers who contemplate coming to the northern part of the State. Anybody, however, who settles in this section will not find it nearly as productive of honey as almost any of the Northern States. The bees gather just enough honey to winter on (what little winter there is), and an extra populous colony may make a few pounds of surplus; but now for the reason.

The native bee is extremely lazy, working only a short time morning and night. The rest of the time is spent, like the Floridian, trying to keep cool, and no amount of smoking will drive them up in the combs and start them to work. Thinking that queens not indigenous to this climate would surely be an improvement, I had a number sent me from the North, but I found they very soon became believers in the maxim, "When in Rome, do as the Romans do."

Northern Florida would be an excellent place for queen-rearing if it were not for the dragon-flies (Devil's darning-needle of the North). They congregate like flocks of pigeons; and the poor bee, laden with honey, finds it a difficult task to evade so many of its enemies in its flight to the hive. If the queen took her wedding-trip in the heat of the day all this would be avoided, as they seem to gather in large numbers only at evening; but she generally takes wing when most of the bees are flying. If the bees gathered nectar in proportion to the yield of flowers, the amount of honey produced would certainly be large. In February, after the bees are over with wintering, they commence gathering honey from the honeysuckle, yellow jessamine, and, during the latter part of the month, from orange-blossoms; then continues one long list of honey-producing plants and trees, such as black gum, holly, persimmon, gallberry, palmetto, etc. From the two last mentioned they gather what surplus they make. All of the honey is remarkably white and thick. Many persons, who are competent judges, regard that made from orange-blossoms as superior to white clover.

There is a ready sale at all times for honey in Florida. It is now selling at 20 c. per lb.; and during the winter, when every thing is booming, the price ranges from 25 to 30 cents, and sometimes even more. C. MOORHOUSE.

Hibernia, Florida, June 9, 1886.

DISPOSING OF THE HOUSE-SLOPS.

FRIEND TERRY GIVES US SOME PRACTICAL IDEAS ON THE SUBJECT, TOGETHER WITH SOME FACTS FROM ACTUAL EXPERIENCE.

FRIEND ROOT:—There was a great deal of sickness in the family that lived on this farm for some time before I came here. Their physician once told me he felt ashamed of having to come here so much. I think about all of them are now dead. They may not have been a healthy family, but still I feel sure the cause of much of their ill health lay inside of the dooryard fence. My friends, when they heard I had bought the place, said, "Don't take your family there to live; it is an unhealthy locality." After looking around awhile I decided it *was* a bad place to live in, the shape it then was, but that it could be made a very healthy and pleasant home. This is about the shape we found things in: A wing of the house extended over the well, and was used as a kitchen and a place to make cheese, butter, etc. The slops and whey that was not used for feeding, were simply emptied right out the doors. I should judge this had been done for a good many years. About 30 feet away stood the old dilapidated privy, or, rather, the remains of it. This had been in use, say 40 years, and probably never once cleaned out. The soil in the dooryard was a gravelly loam, about 16 feet deep; then came clay. The well was dug down through this gravelly earth and about two feet into the clay. The water in it was simply what soaked through the gravel, and stopped when it came to the clay.

Now, when we consider all these circumstances, is it any wonder it was an unhealthy place? For a few years, such carelessness might answer; but as soon as the earth became saturated with filth, so it could hold no more, it must flow directly into the well. I say, for a few years it might answer. It might as far as the well water was concerned, but not if we had any regard for the purity of the air that we must breathe. Both pure air and pure water are necessary for the most perfect health.

Now, I have been particular in describing all this, because, with more or less variation, such conditions are to be found in very many farmyards. So bad are they in some instances, that it is but little better than suicide to allow them to remain.

I was simply exasperated the other Sunday when the minister told us we must welcome afflictions; for, "whom the Lord loveth he chasteneth." We have had too much of that sort of preaching. Why not urge us to do every thing in our power to ward off sickness and trouble; but when, in spite of our utmost efforts, they do come, then calmly say, "Thy will be done"? All the prayer in the world could never induce God to save a man's life if he has drank too much filthy water, or breathed too impure air. "Providence helps those *who help themselves*." "The sword of the Lord, *and* of Gideon," you know. The Lord will never clean out our filthy privies for us. After we have done our best, then there is some sense in asking for help, or even for help to do our best, but not in neglecting what we know ought to be done, then praying for every thing we want. I am not a preacher, Bro. Root—only a farmer; but sometimes I think a minister would know better how to preach to him if he would go and live with a farmer a year or two.

Well, we tore off that old wing, and let in the sun and air, and used no water from that well for years, but went 50 rods to a spring for all we wanted. Since then we have taken out the well, dug it deeper, and put in sewer-pipe instead of stones, and the water, I know, is pure and nice. The privy is over on the other side of the yard; but that was not necessary, for a coal-oil barrel, sawed in two, is used instead of a vault; and with plenty of dry muck or coal ashes we have no trouble in turning the filthy matter into beautiful flowers. I am, however, intending to change, soon, and build a privy at one end of the kitchen porch, and use large galvanized iron pails. This is for convenience of emptying, and for the comfort of the ladies in bad weather. But now for what I am particularly after in this letter—that is,

THE DISPOSAL OF THE SLOPS.

No wise man, nowadays, will pour them out around the door. They must be carried away, then, either by a drain or otherwise. A good underground drain is handy, but I am afraid to use one. Sewer gas is dangerous stuff, particularly where there are children. I know there are traps to keep it from coming out, but still it is risky. A friend of mine *knew* there was a leak or defect in his pipes, but it was neglected until his youngest child died of diphtheria. Gasoline-stoves are safe, perhaps, if properly used; but a few days since, a lady near here *thought* she turned the fire all out; then she filled the stove. She is buried now, and her husband would give all he is worth if he had never brought that stove into the house. No, we don't want to play with danger where the lives of our families are at stake. There is no drain, nor are any slops emptied inside of my dooryard fence—at least not more than once in a place, which can do no harm. For years I carried the water all away in pails; but last winter I found in Illinois a slop-barrel, on wheels, that is just the thing exactly. It stands by the kitchen porch, and will hold all the day's slops, even on Monday. A boy can draw it away and empty it. Disinfectants can be used occasionally, if desired, but will hardly be necessary, as it gets pretty well cleaned out on washing-day. And then there isn't the danger, when it stands out in the sun and air, that there is from an underground drain. In the coldest weather we may have to use the pails again.

My wife has said more pleasant things about that slop-barrel than she ever did about her oil-stove that cost five times as much, or about her silver teaset that I got her last winter. I have seen several slop-barrels, but none before equal to this. It is neat, cheap, and easily managed. They retail for $8.00, but I shall be pleased to order one for any of the friends who will send me $5.50, unless you, friend Root, will get a lot. The makers wrote me I might get some made here, and thus save freight for neighbors, and I should be pleased to turn this offer over to you. If you have any doubts about their being a splendid thing, write to my wife. I don't have a chance, any more, to look a little sour, when, coming in in a great hurry, my wife meekly says, "Can't you empty those slop-pails now?"

Hudson, O. T. B. TERRY.

Many thanks, friend Terry. Most surely is it true that we can not afford to take any risks; and since we have, by the aid of enlightened science, discovered that such diseases as typhoid fever and diphtheria are largely fed by foul matter in the air we breathe and the water we drink, how great is the importance of being careful! What must have been the feelings of that father when he found that there was even a chance that his child might have met death by the horrible disease diphtheria through neglect and procrastination on his part! Now, friend T., I want you to tell me what you think of my arrangement for disposing of the sewage. The one belonging to our house has just been finished, and I did it in this way: The ground descends on a gradual slope from our back door for some distance. The slope is sufficient so the slop on washing-days passes off freely into the garden; but in the winter time it has been in the habit of accumulating so that the opening frequently needed caring for. Well, a few weeks ago I had the boys dig a trench down the slope close by a row of apple-trees. Along the row of apple-trees was a row of well-rooted rhubarb pie-plants. The trench is about three feet deep and two feet wide. This was filled with stones picked up from the ground, according to the plan of the new agriculture, within 18 in. of the surface. As the drain is perhaps 10 or 15 rods long, the vegetation growing above it, and sending its roots down among the cobble-stones, will, it is presumed, take up and utilize the soapsuds, etc., about as fast as it is made. In case it fails to do so, the trench communicates at several points with our system of underdrains, although it is so arranged as to hold a foot or more of water before it flows over into the underdrains. The open end of the sewer-pipe communicating with this trench filled with stones is against the wall on the south side of the woodhouse, the woodhouse being made of brick. No windows or doors come near this opening. A large funnel, made of stoneware, something like a sewer-pipe, makes it easy to empty in the slops. Now, when I built it I did not think it possible that any gases could come up through this sewer-pipe to do any harm. At present there is no smell at all. Before it passes off, the fresh damp earth has absorbed it all. If foul-smelling gases should, however, be found coming out of this funnel, some other arrangements shall be employed. Perhaps your plan of a slop-barrel on wheels is the best one that can be employed; and if so, I shall employ it. Meanwhile we want a picture of the arrangement, and then we will see about furnishing them at a low price. It seems to me that at least 100 should be made at one time. You may, if you can, get figures on 100, and I will see what *we* can do on them during the fall months, when we have plenty of leisure. A matter that concerns the life and death of the little ones around our hearthstones should never be passed over lightly; and *may God help us* in a determined fight against diphtheria and the whole string of malarial fevers.

QUEENS TO CANADA.

TROUBLE AHEAD.

FOR the past six years *custom* has allowed queen-bees to pass between the U. S. and Canada in the mails without detention, although every first-of-January edition of the Postal Guide during that time has distinctly stated that *samples only* of merchandise are mailable between the two countries; hence the sending of queen-bees through the mails to Canada has been illegal, even if we did put on 10 cts. in postage. Custom, often, for a period of time, has more weight upon the minds of the people than do certain laws, so we lull our conscience to sleep and let custom rule until we are, without warning, rudely awakened. Such an awakening I received the other day by having a choice queen returned by the Suspension Bridge, N. Y., P. M., as "unmailable to Canada." As soon as I recovered my senses I wrote him as follows:

Postmaster at Suspension Bridge, N. Y.,

DEAR SIR:—The inclosed tag, doubtless, you will recognize as one attached to a little box containing a queen-bee and her attendants, which you returned to our postmaster as unmailable matter to Canada. I am aware that the postal regulations say that you are right; but to help advance a growing industry both in Canada and the U. S., postmasters of the past have allowed queens to pass to and from Canada as samples of merchandise (which they really are), much to the advantage of all concerned. I have sent, during the past five years, hundreds of queens to Canada, all of which have gone safely since I wrote "Queen-bee for the improvement of stock" on the tag. Now, will you not please do as former postmasters have done, and help advance our industry? By so doing you will only be following a custom of the past, and receive the heartfelt thanks of bee-keepers in all parts of the U. S. and Canada. Please reply, telling me what I may expect, as I have orders for a score or more of queens from Canada. G. M. DOOLITTLE.

Borodino, N. Y., May 21, 1886.

The following is his reply:

G. M. DOOLITTLE,—*Dear Sir:*—Your letter at hand this forenoon. Postmasters who have allowed bees to pass into Canada by mail have not understood the rulings of the P. O. Department. By reading Note 4 on page 770, in the January, 1886, Guide, and also note 20, on page 753, same Guide, you will see that merchandise is not mailable to Canada. I send to your postmaster a letter which I have from the department, on the bee-question. Please call at the postoffice and see this letter. You can then write to the department, and ask them to remedy the matter. We can not allow them to pass through the mail. WM. CARR, P. M.

Suspension Bridge, N. Y., May 25, 1886.

Upon calling at the postoffice I found the following:

No. 71,924, Canada.
POSTOFFICE DEPARTMENT,
OFFICE OF FOREIGN MAILS,
Washington, D. C., May 6, 1886.

Sir:—In reply to your letter of the 4th inst., inquiring as to the rule of postage applicable to bees addressed to Canada, I have to inform you that the transmission of articles of merchandise by mail between the United States and Canada is limited by the postal arrangement in force between the two countries to bona-fide trade patterns, or samples (specimens), not exceeding 8 oz. in weight, and that articles of merchandise such as queen-bees, sent for sale in execution of an order, or as gifts, are not bona-fide samples, and are not transmissible by mail from one country to the other. In this connection, see Note 4, of Foreign-Postage Table on page 770, and paragraphs 20 and 21 on page 753 of the U. S. Official Postal Guide for Jan., 1886. NICHOLAS M. BELL,
Superintendent Foreign Mails.

To Postmaster at Suspension Bridge, N. Y.

As my friend in Canada was anxious for his queen, I made a block out of ⅜ stuff which would slip into an ordinary envelope, provisioned it, put in the queen and ten bees, securely sealed the envelope, and registered the same at our postoffice, directing it via Buffalo.

To digress a little, I wish to say that this queen and her bees went through in perfect order, although they were securely sealed in two envelopes (the ordinary envelope and the thick register envelope). Does not this show that we take more precaution for ventilation of our queen-cages than is necessary? As soon as I heard the queen was safe in Canada I again wrote the postmaster at Suspension Bridge, telling him of it, and showing him by clippings from letters and the *C. B. J.* that queens were passing nearly every day to Canada by mail. I especially requested that he would allow queens to pass the lines until arrangements could be made and a new law rendered, allowing queens to pass legally. I also asked him how he came to stop queens now, when he formerly let them pass. Here is his reply:

G. M. DOOLITTLE:—Your letter of the 2d is at hand. I am sorry I can not allow your bees to pass into Canada. We have allowed them to pass until quite recently, and then stopped, only on receiving a letter from Washington, from the Supt. of Foreign Mails. I shall at once refer your letter to the department, and hope they may make satisfactory arrangements. WM. CARR, P. M.

Suspension Bridge, N. Y., June 4, 1886.

Now, friend Root and brother bee-keepers, what are we to do? It seems to me that the mutual interests of the bee-keepers in Canada and the U. S. demand that a law shall be passed, allowing us the privilege of sending queens by mail from one country to the other. But how are we to get such a law? "that's the question." I have written to the Superintendent of Foreign Mails about the matter. Had each and every apiarist better do so, or can we bring the matter about through the Bee-Keepers' Union? I had thought that it might be a good plan for that body to delegate Prof. Cook or Prof. McLain, to push the matter through. Prof. Cook did us good service when our own mails were closed against queens. G. M. DOOLITTLE.

Borodino, N. Y.

Friend D., this same subject was agitated several years ago, and I believe it was decided that stock of all kinds, exclusively for breeding purposes, was exempt from duty. If I am correct, we pay no duty now on queens only, sent by express to Canada. For some reason or other, it seems that the Postmaster-General has considered it expedient to enact more stringent rulings in regard to the transmission of queen-bees by mail, not only to foreign countries, but even in the United States. A letter has just been forwarded to us, sent by the Postmaster-General to a postmaster, notifying him that queens *only* were permitted to pass through the mails—no *bees* at all. We forwarded the letter at once to Prof. Cook, and told him if he thought best to take a trip to Washington to see about it, we would take the liberty of saying that money would be advanced to him for his time and expenses, providing he would undertake the task. It would be a serious matter to have queens excluded from the mails, now that such an enormous traffic has grown out of it; and banishing worker-bees seems, at present writing, to be the next thing to banishing queens. If queens can be sent to Canada in a sealed envelope, we can perhaps manage it that way almost as well as we have heretofore. I am not at all surprised that the queen and her attendants had all the air they needed, even though sealed up in two envelopes. I have for a long time been aware that we have been taking more pains for ventilation than there was any need of, unless, indeed, a larger number of attendant bees are included than is at all necessary. It may be that right here is where the trouble has come in. Unskillful queen-rearers have been putting more attendant bees in the cages than is necessary or advisable, and perhaps some of the postoffice officials have been stung. Whatever is the trouble, it needs the attention of every bee-keeper in our country, and it is needed at once.

COMB OR EXTRACTED HONEY.

A SUGGESTION FROM AN EXPERIENCED MAN IN DECIDING WHICH TO WORK FOR.

PLEASE send me a sample lot of about 100 lbs. of the new white-clover extracted, as soon as you have a good article. Almost any kind of honey will bring a reasonable price in comb; but a poor grade of extracted is almost worthless. Suppose I suggest to you that you tell the many readers of GLEANINGS, that when the bees are gathering a good heavy white honey of good flavor, that they run the apiary for extracted; and that when bees are working on inferior pasture that it is much more valuable in comb. I hope to do much more in honey another season. I have a trade that I can keep by always giving them a good article. I should much prefer being out of honey for a month or two than to put up a poor article.

Allegheny, Pa., May 26, 1886. M. H. TWEED.

Friend T., your suggestion is something I had not thought of before in just that way. Very likely an article would sell if put on the market in the comb, when it would be difficult to dispose of it in the liquid state. Will those who have had experience on this particular point let us know about it?

MODERN TRANSFERRING.

A MODIFICATION OF THE HEDDON PLAN.

MR. HEDDON'S plan of transferring is, I suppose, largely practiced by prominent beemen all over the country, and is most certainly a very great improvement over the old way of cutting out the combs; but it is just *two* jobs to every hive. He proceeds to drum out the queen and bees (that is, all he can of them, usually about half), and puts them on frames of fdn., in a new hive; sets away the old hive for 20 days for the young bees to hatch, then goes over the same work again. Now, I undertook a much shorter method, and I think I fairly succeeded.

I had five colonies this spring that were in box hives that I wanted in new hives, so I commenced on them the first of April. My idea was, that if I could get it done before the queens commenced laying it could all be done at one job. I will now give my experiment and results:

I commenced the first one in the evening; it was warm enough for bees to fly. I first prepared a new hive by putting in frames of fdn., and two combs partly filled with honey. I set the old hive a few feet to one side, put the new one in its place, and set up boards about it to make it look as near like the old hive as possible; for if you don't, they will not like to go in. I then proceeded to smoke and drum, as does Heddon, for about 80 minutes, when I found a good-sized cluster in my box. These I shook into the new hive. I next took the old hive away 50 yards from the old stand; took a hammer and chisel and knocked it to pieces, cutting out all the old comb clean; swept off the bees on the grass, where they soon "scooted" back home and into the new hive.

Next morning, about 10 o'clock, I proceeded to try another one. I got it into the new hive all right. At noon I went to dinner and rested awhile. I again went out about two o'clock to see the bees, and found my hive, just transferred before dinner, "gobbled" by the robbers, completely "gone up." I then saw my mistake.

Next day I went at it again with three more to transfer. If I lost all of them this time, I proceeded the same as before, except that I did not put any thing but empty comb in the new hives, and fed them after sundown; closed them up to one bee-space next morning, and watched close for robbers.

Well, now for results: In transferring five hives I lost one by not feeding at the right time. I have just carefully examined the other four, and found plenty of brood in all four of them, and they are building up rapidly on white clover, which is now (May 20) booming. In transferring these five hives I commenced with the first sign of pollen-gathering. I found in one hive 20 lbs. of honey and a small speck of brood, not half worth saving. By commencing this work at the first sign of *pollen* we may, by feeding the transferred colony a week or two, knock the old box hive to pieces and make a clean sweep at one job, for we seldom find any brood at that time, unless it is a very large hive, and well filled with honey in the spring, which does not often occur.

I consider, from my short experience, that this is an improvement on any plan of transferring that I know of; at least, so far as time is concerned, and I think it is reliable. There may be some objections found on further trial. I should like very much to hear from others who have had experience in transferring. Our object is, if possible, to learn the best ways to do every thing about the apiary.

North Springfield, Mo. W. H. RITTRE.

Friend R., the success of your plan depends upon being able to find colonies without brood. I believe it is laid down in the books, that all strong stocks commence rearing brood about the first of January; and about the first of April they should contain quite a quantity of brood. I am well aware, however, that common black bees, without attention, are often without brood when the first pollen commences to come in. Such can be transferred on the plan you mention, with little or no trouble. I have done the same thing in the fall of the year, when a weak colony in a box hive was destitute of brood, and nearly destitute of stores. I did not take the trouble to drum them out, however. I simply bumped the hive on the ground until I bumped out the bees and queen; and if some of the combs went along with them it did not matter much. A frame of brood from some other hive gave them a start in their new quarters, and the transferring was all done in about two minutes. The old combs were, of course, tumbled into the wax-extractor. In our locality, bees seldom have a surplus of pollen at any season of the year. On this account I have always felt that your plan and Heddon's was something of a loss, especially where much pollen had been gathered in the spring, before transferring.

SOME CHARACTERISTICS OF THE SYRIAN HONEY-BEE.

THEY FLY TAIL FOREMOST.

I SAID I liked them, but the like is the same as Mr. Osborn, of Cuba, writes me—they pile up the honey. He says he can stand the stinging of a superior honey-gatherer, which the Syrians are. I have two varieties of Syrians — the Jones-Harrington Syrians, and what Mr. Benton terms the Mt. Lebanon strain. This Mt. Lebanon bee can stand more smoke, and do more stinging, than any other I have yet handled. They scarcely get out of the way of smoke at all. Instead of running down the hive when smoked, they buzz and whirl around, trying to drive off the smoke, and keep trying. They act exactly as you have seen bees when on opening up a nest of ants upon them. If compelled to retreat, it is but a short distance to get breath, and back again in a moment they come, dilating their wings, and driving away the smoke. It seems as though you might smoke them to death before they would give up.

They do more off-hand stinging, or stinging on the wing, than either the Italian or brown bee. In fact, they seldom alight to sting. This is the case with the Mt. Lebanon variety. Even when they have inserted the sting they do not alight, but fly round and round to extract it. During the past week, more than twenty have stung the back of my hands without alighting. They seem to come tail foremost, and come with a vim at that.

I removed the queen of a very populous colony, when they at once commenced the construction of queen-cells, and in ten days fertile workers had filled nearly every vacant cell, both worker and drone, with eggs. This I had never before noticed. I have frequently seen fertile workers depositing eggs after the loss of a queen, and when all hopes were gone of rearing one (no eggs or larvæ within the hive), but it was something new to me to see eggs immediately deposited on the removal of the queen. The Syrians have more fertile workers than any other race I am acquainted with. But few colonies appear to be free from them.

W. P. HENDERSON.

Murfreesboro, Tenn., May 29, 1886.

A PRACTICAL METHOD FOR CONTROLLING SWARMING.

REVERSING THE BROOD-NEST, TO INDUCE BEES TO GO TO WORK AGAIN?

WELL, if I have not beaten the bees in a pretty easy way, and so completely, too, then I am mistaken. I never used or saw a reversible hive until this year; but now I have several in use, and, of course, the natural tendency is to experiment with them.

The first swarm that came out was put into one of our new reversible hives. When the bees had filled the hive with comb as much as they usually do—that is, within half an inch of the bottom-bars of the frame, the hive was reversed, to see what the effect would be. The first three days thereafter being unfavorable for honey-gathering, there was no change; but on the fifth day the bees began to build the combs to the top-bars (what was the bottom-bar), and to make each comb solid within the frame, by fastening it on all sides to the wood. All this was natural enough; but here is another experiment no one has thought of—or, at least, no one has mentioned it up to date. I had transferred about ten colonies from frame hives to the new reversible frames, and wanted the bees to stay in them and work in sections, but they would swarm in spite of me; after thinking the matter over for a while, and considering how best to get the better of the little rascals, and keep them at work in the old hive, and also to keep the old queen laying, and the colony in good working condition, I hit upon the following plan:

When a swarm came off I removed the queen-trap and sections; and before the bees could miss their queen and return to the parent hive, the brood-nest was reversed. By and by the bees returned and entered the old hive as if nothing had happened; and while they were going in, the queen was released from the trap, and the work was done. Now, the fine little trick I played on the bees was this:

When the bees entered the old hive and found the combs, queen-cells, and all reversed, they were so surprised and astonished that they really thought they had been hived, and were occupying a new house, and the idea of swarming again was given up. By this operation the "wind is completely taken out of their sails," and is what I call using the reversible hive to some purpose.

The time required to reverse the hive is not over one minute, and the time required to hive the new swarm is none at all; as the bees, when the trap is used, will hive themselves. Now, I have pointed out a few of the advantages of using the reversible hive and queen-trap. If the above operations are not strictly practical, there is a chance for some one to "get up" and explain. There is not the least objection to such a plan, as I am sure no colony will attempt to swarm again after being thus treated. By adopting the above, it seems to me swarming may be completely controlled.

Wenham, Mass. HENRY ALLEY.

Your suggestion is certainly an important one, and no doubt it can be made to answer a good purpose, although I am a little inclined to think, from what experience I have had with swarming, that the plan will not "always take the wind out of their sails," as you express it. Very likely the experiment will be tried by a great many, as it comes in just the right season. Almost any hive can be prepared in a short time so that it may be reversed after swarming, and still keep the surplus-receptacles in their usual place right above the brood-nest. If any others have tried the plan, will they please report?

LETTER FROM CHINA.

SOME VALUABLE FACTS FROM OUR MISSIONARY FRIENDS.

WHEN I first came to Foochow, which place is only a little north of the tropics (N. lat. 26° 7′) I found that well water here was not nearly so cool as it is in Oregon or Maine. Now, we are very sure that the interior of the earth is hot, while the temperature of the surface of the ground varies with the temperature of the air. But the amount of this variation decreases as we descend into the earth, so that at a depth of 30 or 40 feet we ought to find a nearly constant temperature the year round; and this temperature can not differ much from the *mean* annual temperature of the air above; hence, well water and spring water are much warmer in the tropics than in the temperate zones.

At Shau-wu a Chinaman ventured the remark that well water was warm for the winter half of the year, and cool for the summer half of the year. It seemed so to him, because throughout the colder half of the year well water is warmer than the air, and so at the first touch feels warm to the bare hand. You don't notice the same thing in your northern climate, because your houses are warmed by stoves; and then, too, the difference between the temperature of the well water and the hand is much greater with you there than it is with us here. Then, again, this Chinaman probably never drank well water in cool weather. He would not dare to. Our well at Shau-wu is about 25 feet deep, and has a temperature of about 67° Fahr. in summer and 63° in winter.

Recently in traveling among the mountains I took the temperature of several springs. One of these, about 1300 feet above the sea-level, had a temperature of 62½°. It is quite a copious spring, comes right out from the bowels of the mountain, and its temperature hardly varies the year round. Another spring, 500 feet higher up, had a temperature of 55°. I once tested its summer temperature, and I think it was 58°. In that region is a mountain about one mile high, and near the top is a monastery. I once visited this in the hottest summer weather, and in it was a well, the water from which was so icy cold that it made my teeth ache so that I could not drink it with comfort. A Chinaman who accompanied me said it was so cold that it "bit the teeth."

Three weeks ago I crossed a mountain-ridge about 3000 feet high. The water in a spring on the north side, 1500 feet high, had a temperature of 57°. Six hundred feet higher was another, with a temperature of 54°. Near the top was a third, with a temperature of 48°. Coming down again about 2000 feet on the south side of the mountain, a fourth spring, flowing from a seam in a ledge of rock, had a temperature of 64°. In each case I presume the temperature of the spring was not far from the mean annual temperature of the place where it was located. In high northern latitudes the ground freezes in winter to the depth of 20 feet or more. J. E. WALKER.

Foochow, China, April, 1886.

Friend Walker, is it not probable that these very cold springs you speak of, high up on the mountain, have some subterraneous connection at still higher altitudes, where snow and ice prevail? I suppose it is true in China, as well as in other parts of the world, that the highest peaks are covered with snow, even in the summer time; but even if not covered with snow, I suppose the temperature would be down to about the snow-point, and this might lower the temperature of the water so as to cause it to remain low, even after it issued from a spring several hundred feet lower still. We thank you for these interesting facts.

PREVENTING INCREASE.

HOW I HAVE TRIED, AND FAILED.

DURING the four seasons — the fifth now began — in which I have followed apiculture, I have made the production of comb honey a specialty, devoting some attention to extracted honey, and I endeavor to make all my operations subservient to that end. To do this, the most difficult problem that confronts me is that of swarming—not how much shall be allowed, but when and how shall it be done? I want to prevent much increase, and to that end I have read, studied, and labored. Last year's efforts were largely spent in showing how the plans of Cook, Heddon, Doolittle, and others, do not work. Every scheme I try to prevent swarming fails. The difference in locality will largely account for this, but not altogether. Dr. Miller's plans I have not tried, chiefly because of the time and labor involved.

I am now going to give the results of my experiments of last year, for although I have learned chiefly what can *not* be done, I am certain that I am much nearer a solution of the problem than ever before.

THE A B C PLAN.

I have repeatedly tried the plan given by Mr. Root; viz.: Take a frame of eggs and newly hatched larvæ; put it in a hive filled out with empty combs or frames of fdn. Move the old hive off, and put the new one in its place. Of course, the new hive will catch all the flying bees—or else it won't. I have known nearly all of them to remain with the old stock. Over half the time the old colony will swarm some later, unless I weaken them down so that they will do me no good during the season; while the artificial colony will often loaf in an almost empty brood-chamber until the queen is hatched and laying. Every time I tried that plan this year I failed.

PLANS OF MY OWN.

I have tried moving the queen and one or more frames to some other location. The bees left in this queenless colony do nothing but build queen-cells, and proceed to swarm as they hatch, providing I do not destroy the cells after the larvæ are all sealed up.

I tried the following expedient with several stands last year: I removed the supers, took out six of the eight frames, gave them two or three shakes, set them with the few bees still adhering in a new hive, and moved them off to a new location. I put one of the remaining frames in each side of the hive, filled up with frames containing starters, and put on the supers again. Every one of them swarmed soon afterward. I took out the old frames of brood, putting frames of fdn. in their places, and put the swarms back. Two of those came out afterward, leaving eggs and brood, and scarcely a bee to take care of the poor helpless infants.

THE ABOVE PLAN WITH NATURAL SWARMS.

With several natural swarms I tried thus: I put a frame of sealed or unsealed brood in each side of a new hive filled up with frames as above, hived the swarm, set them on the old stand, and put on the supers. All but two swarmed out again in from two hours to eight days; and those two showed signs of discontent for three weeks afterward. In all the above cases I had destroyed all queen-cells.

Again, last year I tried several times hiving a swarm in a hive that had recently sent off a swarm. Every one came out again in from three hours to three days, except two that were thus hived after the honey-flow had ceased. From some of these, by the way, I had removed about half the frames.

I regard it as a significant fact, that out of some 30 swarms absconding thus, only two have ever left the apiary. They always settle, and, when hived more to their liking, go to work as busy as—bees.

MAKING NEW COLONIES FROM SEVERAL OTHERS.

Prof. Cook says, that by taking one or more frames from several different colonies, and forming new ones, he can allay the swarming impulse. I do not know that the plan has ever succeeded with me, while I do know that it has failed a number of times.

SWARMING IN MAY.

I intended to make several artificial swarms, and form nuclei in May last year, but I was disappointed in not getting the queens I wanted in time. I did swarm two toward the last of the month, greatly weakening the stocks containing the old queens. They both swarmed about a month later.

WHAT DOES IT ALL MEAN?

If the above array of facts means any thing, it means that bees want to swarm; and that when they do, they want to set up housekeeping anew. After-swarms are more apt to stay when hived on frames of brood; but even they will loaf until the queen gets to laying.

NEW SWARMS DO NOT OBJECT TO HONEY.

While I say that bees want to go to housekeeping anew, I have never yet seen any indication that they object to a lot of honey in the upper story. My bees do not swarm until they have begun to store honey considerably. I always put on sections as soon as honey begins to come in plentifully. Last year I hived my swarms in new hives on new stands, leaving the half-filled boxes on the old stand, hoping that they would prevent after-swarming, but they never did. Following Heddon's teaching I put the surplus arrangements on the new hive and set the hive on the old stand. They go right to work in them, as if nothing had happened.

WHY MY BEES MUST SWARM DURING THE HONEY-HARVEST.

My experience convinces me that Mr. Doolittle's method of artificial swarming will not work here. His harvest comes in July. He has all of June to build up and do his swarming, and well may he make three colonies out of two within a week before that season sets in. But here, swarming and honey seasons come alike in June. Our vernal season is generally cool and backward of late years. I have never yet had a good yield from fruit-bloom; consequently, something like the horse that is blind in one eye and can not see out of the other, one-half of my bees diminish and the other half do not increase. That is a *little* stretched, however. About June 5th, white clover begins to yield copiously. Possibly one-third are strong enough to swarm in the next ten days. The rest will swarm all the way from June 15 to July 15. They take their time to it; but *swarm they will*, and don't you forget it. They do not quit when honey quits. Now, I do not give it up. I have already planned to do some artificial swarming this year, and I hope to meet with some success. But, so far as I have learned by experience, I see no way to do but to let them swarm.

OVERRULING.

But if we can not prevent we can overrule swarming. This is what I mean by overrule: Hive your swarm; put on supers, whether you had them on the old hive or not; set the hive on the old stand. Take the combs and remaining bees from the parent colony and unite them with one, two, or half a dozen weaker colonies, according to their strength. Work them so that the rapidly hatching brood will soon have those weak colonies booming, and put on supers at once. I have several colonies at work by this means that otherwise would have done me no good at all. I think the plan preferable to Mr. Doolittle's plan of uniting weak colonies before the honey-harvest, at least in this locality.

Mechanicsburg, Ill. GEO. F. ROBBINS.

Friend R., after you have tested these plans through a longer term of years, I think you will find that, as a rule, in many seasons you will succeed better. Your bees seem to have had a sort of swarming mania; and when they go at it in that way, I have oftentimes thought it was best to let them swarm. Where I was very anxious to have them finish a set of boxes, I have succeeded by removing the old hive to a new stand, and hiving the swarm in it. They had a new location, even if they did have their old hive and partially filled sections. Sometimes giving a large amount of room in the brood-apartment seems to satisfy them. At other times, nothing short of a new location will answer; but when they *are* satisfied, they go to work with such a vim that it seems as if it were worth while to humor them some. In friend Terry's new book on horses and cattle, he tells us how he got large yields of milk from an eccentric cow. He conceded to her whim, and she paid him by a great yield of milk; and altogether it paid to let her have her own way. Is it not often the case with a colony of bees, when they want to start out in a fresh home?

MARKETING HONEY, AND ITS WINTER CARE.

THE RESULT OF OPEN WINTERS.

THE same general rules which guide us in marketing extracted honey are applicable in the case of section honey. It should be made attractive to the eye and satisfying to the taste, and should bear the name of the producer upon each package. The greatest care should be taken to prevent the surface of the comb being soiled or broken. If so disfigured, it should not be put upon the market unless it can be sold without the producer's name. The sections themselves should be scraped and sandpapered till they shine, and the crates should be either white and clean, or nicely stained or painted. Each package should "set off" its contents. Honey should not be sent to market in the half-stories, or cases of the hives, but in nice white crates made for the purpose, with glass at one side at least. There is a great deal in a show of honey, and so the more of these crates piled up in a window the better, because the honey is made more attractive, as also more conspicuous. The winter care of honey is important. Extracted honey, if not kept in a constantly warm place, will granulate; that is, it will become hard and white, and appear much like lard. Many people think this change in honey is a sure sign of adulteration, and begin to talk of sugar, but such poor creatures do really deserve our pity. But we must overcome a just contempt on our part before we can bestow such a sympathy. To reliquefy honey it is only necessary to warm it slowly and thoroughly. Proceed as follows:

Take a tin or iron vessel of sufficient size, and place inside it a wooden block or light iron grating of some kind, about half an inch high, and large enough to support the vessel containing the honey. Place this latter vessel upon its support, and fill the outer one with lukewarm water as high as possible without covering the honey. Remove the lid from the honey, and place the whole affair over a slow fire; keep the water just under the boiling-point till the honey is all melted. Seal up again while warm. Section honey should be kept where it is dark, dry, and warm. The light will spoil the color of the capping; damp will burst the cells and sour the honey; and cold will granulate the honey.

The winter of 1884 was so severe that our bees neither required nor could get much care. The greatest trouble in open winters is on account of the tendency bees have to fly when the weather is unsuitable, and the constant uneasiness among them. They are disturbed every few days by the heat, and do not really settle down quietly enough to winter well; and as a consequence of all this they consume far more honey than is good for themselves or their owner; and often, before the latter is aware, the honey is all used up and the bees starved.

Another trouble consequent upon the large consumption of honey is a great tendency to dysentery. Our endeavor should be to keep the temperature of the air within the hive as unvarying as possible. With bees packed in the cellar or bee-house, we shall have little trouble; but with those in the clamp it is another matter. During severely cold spells the hive-entrances should be kept almost closed; in "reasonable" weather they should be wide open; and during mild spells, open, and shaded from the sun so as to keep the air as cool as possible inside the hive. During warm spells, when there is no wind, and when the air is really warm, leave the entrances open and unshaded for a few hours each day, that the bees may fly. At all times keep the entrances clear of dead bees, snow, ice, etc. Protect from all wind, and give the bees candy during flying spells, when short of stores. Don't let them starve. MATHIAS SCHNEIDER.

McIvor, Mich.

WHAT KILLED FRIEND MILLER'S FIGWORT?

A YOUNG LADY SHOOTS THE BEES.

LIKE Rip Van Winkle I have been sleeping for a while, but not for twenty years, so far as being heard much about the bee-business is concerned, so here I come again. I think I can guess what killed Dr. C. C. Miller's figwort. Last year about this time I had several rows of figwort in my garden. It was in its second year's growth, when I noticed it looked yellow and sickly, and did not seem to grow much, when one day I was hoeing in it and discovered that something was working at the roots; and on further search I found the roots were nearly all eaten away by a large worm which, on first sight, almost any one would take to be the common cut-worm that is so destructive in gardens and cornfields; but on a closer inspection they proved to be a different species altogether. They were a light pink, or flesh color, and from one inch to an inch and a half long, and their work was different from the cut-worm, as they went inside of the stalk near the ground and then went down into the roots, which they ate out clean, excepting the bark. They seemed to prefer two-year-old roots rather than one-year ones.

As soon as I made this discovery I began digging up all of the plants, and could find generally from four to eight, and in one case I took as many as fifteen worms from a single hill. This disgusted me with the figwort, so I dug up all I had, and don't let a stalk grow since, although thousands of young plants are coming up all the time now.

The other day, as a bee-man a couple of miles from here was going to the field to work he told his daughter, a buxom lass of 18, that a certain stock of bees didn't act right, and told her to watch them, and if they swarmed, and tried to go off, to shoot them, looking at his wife, and laughing as he said it, but never dreaming she would do any thing of the kind. But pretty soon, out came the bees; but not making any attempt to alight, they rose right up from the hive and began to work away. She, seeing they were going, concluded something must be done to stop them, so she ran into the house and grabbed a shot-gun loaded with a heavy cartridge of shot, and out and after them. By this time they had got off quite a piece, and were rising rapidly in the air, in a funnel-shaped cloud, and were getting nearly out of sight, evidently fixing for a long flight, when she raised her gun, braced herself, and, pointing the muzzle straight at them, blazed away. She says a shot bird would not have dropped to the ground any quicker than those bees did, where they clustered on a little bush, and she hived them at her leisure. Well, that shot took the romance all out of them, for they went right to work like good bees. This morning I brought that swarm to my apiary. A. A. FRADENBURG.

Port Washington, Ohio, June 17, 1886.

It may be, friend F., that the failure of figwort, after standing two or three years, is owing to some such worm as you describe, that feeds on the roots, although we never discovered any thing of the kind when we plowed up our old plantations.—Bringing down a swarm with a charge of shot is a rather new idea, but not so very improbable after all. We have had many reports indicating that throwing dirt, sticks, or stones, through a swarm just as they are getting ready to move off demoralizes them so as to cause them to cluster. Perhaps the shot did the same thing in the case you mention. Where it can be done conveniently, we wish some of our bee-keeping friends who have shot-guns handy would give it a test. Firing guns so as to disturb the bees by the sound has often been recommended; and may be that sending a charge of shot right through the cluster has before been recommended, but I do not now remember of any such case.

"GETTING BEES OUT OF SECTIONS."

FRIEND HEDDON'S METHOD.

I HAVE quoted the above heading from brother Miller's article on page 475. I think I am safe in saying that we all thank friend M. for shedding more light upon this practical subject; but, after reading his article, I felt as though I could add a little more brilliancy to the torch before I passed it along.

First, let me say, that, years ago, I tried the doctor's plan of opening several hives at a time, in order to facilitate matters when driving the bees down with smoke. When they were at all inclined to rob we blew the smoke through a wire-cloth frame laid over the top of each of the supers, opened. We didn't like the plan, and abandoned it. The one which I will now describe, and which is more briefly described on pages 80 and 81 in my book, suits me the best of any method I have ever tried or heard of.

You know we use a one-story case holding 4¼ sections, open top and bottom, all cases being interchangeable, and used on the tiering-up plan, as described on page 80 of the book above referred to. By the above system the most finished cases are always on top; and when we find one ready to come off, we remove the cover, and quickly and sharply puff smoke into all the ranges between the combs. With our mouth we now energetically blow between all the ranges, and we do both as quickly as we can write these words. No bee is hardly allowed time to commence to fill his sack. More than four-fifths of the bees immediately descend out of the case. We now quickly lift it, cover the hive, and, holding it over the alighting-board, shake it with a jerking, tremulous motion—a motion that, above all others, will dislodge the foot-hold of bees—and I think I am safe in saying that not over 50 or 100 bees remain. We now carry the case to our screen-house, which is described in our book on pages 56 and 65. Here the cases are stood on end, standing on each other when lack of room requires; and as the light passes readily through these shallow ranges from either side, the bees leave the cases in a few moments, when the screen-house doors are opened and all the bees are ejected into the open air in an instant. All this is done with such dispatch that the robbers can not get the first taste, even during times of honey-dearth, when most persistent.

We have found the above method as speedy and practical in the apiary as it looks on paper. It has given us great satisfaction, and we can't imagine how the method can be excelled. Of course, it would not work well with two-story supers, or closed-top sections; but we do not lament this fact, because there are so many other reasons why we could not be induced to use either.

Relative to this subject, I wish to mention a principle among bees, not mentioned among others, and, I believe, not usually recognized. Ancient authorities have told us that smoke, or any thing else that frightens bees, saves us from being stung, because, when frightened, they fill themselves with honey, and, when so filled, neither desire to nor can they sting. Now, I have found that the *fright* they receive is what prevents their stinging. I mean "fright" direct, no matter whether they fill themselves or not. With smoke, I have perfectly subdued very angry swarms while clustered upon a branch or fence-rail. JAMES HEDDON.

Dowagiac, Mich., June 18, 1886.

Friend H., your suggestions indicate beyond question that you have had experience in the matter; and since you mention it, I remember that we used exactly the same plan to get the bees out of the sections years ago. The tremulous motion looses the bees' foot-hold, and then a quick shake will tumble them out pretty rapidly.—I am glad you have decided to use none but open-top sections, for almost every season we have more or less complaints from parties who wanted closed-top sections, only they forgot to say so. Some go so far as to say they would not take open-top sections as a gift, and ship them back before waiting for orders. In vain have we told them that the openings could be closed by means of strips of wood or enameled sheet. They had their own notions of things, and would not be pacified. Of course, we are always glad to make closed-top sections where people want them; but where nothing is said about the openings, we always send the regular goods.—You may be right, friend H., in saying that bees may be *frightened* into subjection, without filling themselves with honey at all; but we have been so much in the habit of subduing them while on their combs, with honey right before them, that it has never before occurred to me the same thing might be done without any honey at all. By the way, after you get the bees out of your cases of sections, how do you send your honey to market? You may have told us about it; but if so, I have overlooked the fact. Tell us a little just how these one-pound sections shall be handled after we get the bees out.

HEADS OF GRAIN
FROM DIFFERENT FIELDS.

HOW AN A B C SCHOLAR HAS SUCCEEDED, AND RESULTS.

AS I see in GLEANINGS you notice even the least of bee-keepers, I thought I would tell you my experience. I live in an excellent farming section, with lots of basswood. In the spring of 1884 I bought a swarm of bees of Mr. Harrison. They were in an old-fashioned box hive, fair hybrids, and very strong. They "hung out" all summer, but did not swarm. I got very little white honey; but in August they were transferred into a Quinby hive, and made about 10 lbs. from the buckwheat flow. Last year they swarmed twice—the first, July 13th; the second, July 22d. I had them packed in the most careful manner possible, six inches of chaff on each side, except the front, and the upper story filled. The first swarm filled their hive (every frame was filled with empty comb), and made about 25 lbs. of as nice basswood honey as you ever saw packed in 1½-lb. sections.

The second was hived in an old box hive, and wintered well, though only half full of comb. I fed them 5 lbs. of granulated sugar. All three were packed as well as I know how. This spring, while two had wintered finely, the first swarm of last year was dwindling to a pint of bees, with a patch of brood as large as the palm of your hand. I put them in a nucleus hive to hold two frames. The next day they swarmed out till there were not three bees left in the hive. In a few minutes they came back. I think they lost their queen in this sally.

On opening the old hive, in the latter part of April, I found solid sheets of brood and drones capped over. Last week, with the help of Mr. Harrison (my confidential friend in bee-keeping) I transferred the box swarm. We had poor success. The combs fell down, but I threw away all but the brood, and put in sheets of comb built on foundation. It was his second attempt, and I had acted as an assistant at one other. I can't tell how it will get along now. I am a great enthusiast on the subject of bees.

In my limited experience I have found bees to store pollen in the side boxes, but not in the upper story. I am reading your A B C book. My account in the bee-business would be as follows: Expenses for hives and bees, $6.50; value of honey, $6.00. Value of bees, $10.00. Profit, $9.50.

JARED VAN WAGENEN, age 14.

Lawyersville, Scho. Co., N. Y., May 3, 1886.

SHALL WE PERMIT MISLEADING OR FRAUDULENT ADVERTISEMENTS IN OUR COLUMNS?

I inclose a clipping from a paper. Can you put it in labels, and also put your name below it? I admire such a stand as this by any editor, and only wish that more of them would do as this one has done.

Duarte, Los Angeles Co., Cal. W. W. BLISS.

Below is the clipping referred to above:

> We will not publish, for any price, any patent-medicine or lottery advertisements, or humbugs or "sells" of any kind.
>
> Our advertisers are all reliable men; and if subscribers, in opening a correspondence with them, and also in any order they may afterward give, will state that they saw the advertisement in *The Baltimore List*, we will guarantee that they will receive fair dealing in every instance.

Friend B., we have, as you may know, for several years insisted that our advertisers be responsible men. As we once suffered considerable loss, however, because one of our bee-men, who had hitherto been considered good, failed in business, we have thought best to change the wording of our guarantee a little. It is not always an easy matter to draw the line between advertisers who advertise with a deliberate purpose of fraud, and those who lack judgment, and make a failure. The former, we can readily guard against; and we always shut down on the latter when we think the circumstances warrant.

WHAT CAUSES WAX TO CRUMBLE?

I have been trying to make a little foundation, and find, after working my wax a short time, that it gets tender, and crumbles. Thinking perhaps you would be kind enough to tell me what the trouble is, I come to you for information. Would a little paraffine help the matter any? Bees are doing finely. D. J. SPENCER.

Hartford, O., June 3, 1886.

Wax becomes brittle by working, in consequence of being heated hotter than is necessary; also, after being melted many times over, it becomes crumbly, as you mention. There is no remedy that I know of, unless it be adding a considerable quantity of fresh wax. We have had specimens of wax that seemed about like Indian meal; and, failing entirely to get it to run together, we sold it to the wax-bleachers, to be used for making wax candles. By no manner of means add paraffine. See our caution in regard to its use, in the A B C book.

WHY DO MY BEES BUILD DRONE COMB?

I should like to know how it comes that the bees build nearly all drone combs, or why they do so in this locality. All the new frames that I added to the brood-nest in parent hives had worker foundation. Every time the bees start drone combs, they are storing surplus fast, as there is a great flow of honey here at the present time.

JACOB S. WEIBLEY.

Kistler, Perry Co., Pa., June 5, 1886.

Bees naturally build drone or store comb during a heavy yield of honey, because the same amount of wax and the same amount of labor will contain a greater quantity. Drone combs in the surplus-receptacles will do no harm unless they injure the looks of the comb honey. The remedy is to use foundation, instead of letting the bees build their own comb.

HOW TO GET RID OF DRONES.

Could you tell me the best way to control the breeding of drones? Are the "drone-guards" advertised, good for the purpose? Also what will remove propolis from the hands and cloth covers?

J. H. SCOTT.

Gaylord, Otsego Co., Mich., May 21, 1886.

The drone-guards are exactly the things, friend S. Printed directions on the paper that is wrapped around them will give you all the instructions you need. We control the breeding of drones by the use of comb foundation.—The best thing to remove propolis that we know of is a soap that we advertise for the purpose, called "scourine." Benzine will also readily dissolve it, but it is dangerous to have about. Notice what friend Terry has to say about the use of gasoline.

WAS THE QUEEN LOST IN THE SWARM? OR WHAT MADE THEM ACT SO?

I had my first swarm yesterday morning, and I want to ask if I did right in the way they were hived. The bees flew around near the hives for about 20 or 25 minutes, then went in the direction of a small swamp, and first alighted on a board walk that crosses this marshy ground. They were not in a compact mass, but scattered over a distance of three or four yards. I tried to sweep them into a cloth, but did not succeed. They then went about 15 yards, and alighted on the grass at the edge of the swamp, in about 10 or 12 bunches about the size of large potatoes. I succeeded in getting them hived by placing over them a part of an old box hive. They would crawl into this, then I would shake them in the top of the hive; I got them all in except a few scattering ones, then moved the hive about 300 feet away on the other side of the house; but in half an hour they had left the hive, and I can not say where they went. I thought they had gone back into their old hive, as there seem to be as many bees there as before, and that the queen was lost in the swamp. Did I do right in hiving them before they were in a compact bunch?

0—JOHN L. KUGLER, 4.

Philadelphia, Pa., May 24, 1886.

Friend K., I think I should have waited until the bees collected in one compact cluster. This would be an indication that the queen was with them. Whenever there is any doubt about having secured the queen, a comb containing some unsealed brood should be given, or they will surely desert just as yours did.

TRANSFERRING FROM LOG HIVES; ALSO A KIND WORD.

We take pleasure in acknowledging the receipt of the goods sent us. We now thoroughly understand the one-piece section, and say they gave perfect satisfaction. We started in the fall with 25 colonies, nearly all in hollow log hives. We lost 2, and have now 23 colonies. We transferred into the chaff Simplicity hive. Some of our old hives were hollow gums, and could not be split; so in order to transfer them we laid them on the side and nailed strips along them so as to guide the saw, and sawed them open with a cross-cut saw. We have 408 sections in 17 colonies, most of which will soon be ready to take off. We live almost on the backbone of the Alleghanies, where the mountain-sides and deep ravines are covered with locust, poplar, basswood, etc., and we find the bee-fever is a little contagious among those who come near enough to see the sections filled with beautiful white comb honey, ready to cap over within three to five days. As a remedy for their disease, we have advised them to take GLEANINGS. Don't you think it would help them?

HOUCHINS & HUGHES.

Pipestem, W. Va., June 7, 1886.

CENTRAL VIRGINIA FOR BEE-KEEPERS.

I have long wanted to write a few lines, showing our bee-keeping friends the advantages of this section. In a few words I will tell the facts. We have a mild and healthy climate; pure air, and an abundance of excellent water; freedom from malaria and mosquitoes; soil good, and easily worked, and not liable to droughts, though much of it is stony and hillsides. Apples and pears grow finely and of excellent quality; peaches grow well, and yield excellent crops when not cut off by frosts. Grapes, and all the small fruits, do admirably. Roads and schoolhouses are already built. Bee-pasture is in abundance, and mostly going to waste for want of apiaries. Much of the above applies to the whole of the Blue Ridge, though some localities are better than others.

There are two points worthy of regard—the difference of elevation of the hillsides causes a lengthening of the flowering season. From our house to the foot of the hill (three miles by the road) makes a difference of ten or twelve days in the blooming of the yellow locust, thus prolonging the honey-gathering days; and then the tenacity of the seeds of the red clover. I have plowed under the second crop of clover when the seeds were ripe; cultivated two crops of corn on the land, then plowed the third year, and raised an excellent crop of hay without sowing any more seed, and this can be done, rotation after rotation, with clover, corn, wheat, or rye, indefinitely. Catnip grows on all our hillsides. Raising fruit is done very profitably, and land can be bought so cheap that I believe a good investment would be to pasture sheep, raise bees, and let the yellow locust grow up spontaneously till they are large enough for fence-posts.

A. H. VAN DOREN.

Liberty, Bedford Co., Va., June, 1886.

HOW TO USE THE JONES GUARD.

You say in your catalogue that the Jones bee-entrance guard can be fixed over the entrance when the drones are all out, and at night destroy the drones. Now, I should like to inquire if there *ever* is a time when the drones *are all out;* and if so, when is it, and how early in the season will it do to destroy them?

A. J. W.

Macedon, New York.

During the warm months of the year the drones begin to take their flights from the hive about 1 P. M. By half-past one, most or all of the drones will be out; so if the guard be attached to the entrance soon after, the returning drones will be shut out, and may then be disposed of. The few remaining drones, if any, will be young drones, and can be gotten rid of in like manner. If more convenient, having found the queen, all the bees can be shaken off the combs in front of the entrance. The workers will readily pass the guard, and the drones will be excluded. See page 461.

THE MARKED SUPERIORITY OF ITALIAN OVER BLACK BEES FOR WORKING ON RED CLOVER.

I have noticed lately in one of the bee-journals that some writers go back on red-clover bees, and say that the idea of such bees is all "bosh;" and as I have had some experience in the matter I will just throw in my "mite." While living on a new place, some nine miles from here, I seeded six acres of fallow ground with "mammoth" red clover—not peavine. It caught well, and the next year it was a perfect sea of bloom, and at that time there were 3 colonies of Italians and 75 colonies of blacks in the neighborhood. When I cut this clover the bees were at work on it vigorously; and by actual count by myself and hired help there were five Italians to one black bee. We counted the bees in a number of places in the field, and found them to average as above. I would give $25.00 for a colony of bees that would work on red clover as vigorously as did those. These bees were raised from a queen sent out by Mr. M. Quinby, just about the last of his shipping queens, and they were the prettiest Italians I ever saw. GEORGE A. WRIGHT.

Glenwood, Susq. Co., Pa., June 2, 1886.

HOW DO BEES CARRY WAX?

Is it a fact, that the bees use their pollen-baskets for the purpose of carrying wax as well as pollen? I was greatly amused several days ago at a sight I never saw before. When I was putting on my surplus boxes the fdn. dropped from one of them, and so I laid it on top of one of the hives. As I was passing that way later, my attention was called to the hive, where I discovered several bees at work on the piece of fdn. They would nibble it off with their mandibles, and then pass it back to their pollen-baskets, and put it on so that it would stay there. I noticed they worked at the fdn. all the afternoon.

The prospects for a good honey-flow were never better in this section than at the present time. The season is about two weeks earlier than usual. My bees are all very strong, and are gathering honey slowly; but I expect in a few days that they will begin on the white clover, which is just blooming out. Now, while we in this section do not have such honey-flows as we read about in GLEANINGS, yet I had one colony store 40 lbs. of clover honey in 1-lb. boxes. I often see in GLEANINGS where yourself and others speak very highly of clover and basswood honey. In this part of the State we have an abundant flow of honey from a small white flower which surpasses all clover or basswood honey I ever saw. It is a wild shrub, and blossoms in August. I may send you a sprig of the flowers, if I have time to get them, and box them up when they are in bloom this summer, and perhaps some of the honey too. I am sure you will pronounce it excellent, as my customers all do.

10—GEO. W. BENNETT, 15—33.

New Bedford, Mass., June 7, 1886.

Friend B., the matter you mention is not at all new. Bees will often stop work right in the height of basswood and clover bloom to collect wax, in the way you mention. I am inclined to think they use it as they do propolis; and I have imagined that they become more eager for gathering wax, varnish, resin, or different kinds of gum, when we begin to have cold nights. It seems to me that they begin to feel an instinct prompting them to shut up cracks before the approach of winter. Perhaps you had been having some approach to cool nights about the time you wrote, and this set the bees in a mania for hunting propolis.

HYBRIDS — AND WHAT IS A HYBRID BEE?

If I understand rightly, an Italian hybrid is the result of a cross of a pure Italian queen with a black drone, and that her drones are pure Italian. Will the drones from her daughters be pure to cross with Italian queens? Are the progeny of a black queen crossed with Italian drones, as cross and as good as the others? F. CLARE.

L'Original, Ontario, Canada, June 9, 1886.

Friend C., the theory is, that the drones produced by a pure queen, even though she be impurely mated, will be pure, or full blood; and I believe all careful experiments corroborate this theory. In view of this, the drones from a black queen mated with an Italian drone will be pure black drones. As to whether the workers will be any different in the first case from those in the second case, is a question. We have very carefully watched the habits of hybrid workers from pure black queens and pure Italian queens. There seems to be little if any difference.

BASSWOOD ON SANDY SOIL.

Will you or some of our bee keeping friends tell me how basswood will do on sandy soil, as I think of starting a grove on sandy land? Maple, and such trees as walnut and locust, grow well here.

ELMER SKINNER.

Morocco, Newton Co., Ind., May 23, 1886.

Friend S., we find basswoods growing naturally on all kinds of soil, although I think they thrive best where the ground is somewhat low or damp. On this account they seem to thrive better in dense forests, where the sun does not strike near the root. We seldom see good strong thrifty basswoods on high hills, unless near springs.

CALIFORNIA BEES PROHIBITED IN CERTAIN FRUIT-BELTS.

Here we are, only thirteen miles from the beautiful city of Los Angeles, of which we had heard so much, but had never seen; while away in the distance we view the snow-capped peak of "Old Baldy," which reminds us of "Old New York," our old home, three thousand miles away. Although I am but 19 years of age, I have read GLEANINGS for three years, and could not get along without it.

Bee-keeping is prohibited in the fruit-belts, owing to the alleged injury to the fruit, done by the bees. As I have been in the fruit-region only, I have seen but few bees, and consequently I am unable to give you a satisfactory idea of the trials and tribulations of the Californian apiarist; but as I intend to travel from Los Angeles to San Francisco on horseback, I shall probably see a great many bee-ranches, as they are called here, and shall then be able to tell you about bee-keeping here.

To those who are thinking of coming to California to reside, I will say, Come and see the country before you bring your family, for no description could convey to you a correct idea of this country, as it is so entirely different from the East that it seems like another world. People here speak of the East as "The States." C. E. HUTCHINSON.

Fulton Wells, Cal.

A "DRONELESS" COLONY.

I have a hive of bees that are droneless. They were a late swarm last year, but did nicely, and are still growing. They are getting to be "immense." Will you please inform me as to the probability of their swarming without drones? I have looked the A B C book through, but do not find any thing upon that point. Can there be any thing done to encourage them in swarming? **N. C. ARNOLD.**

Wilson, N. Y., June 14, 1886.

Why, friend A., that is a new idea. We have heard of *queenless* colonies quite often, but I don't know that I ever before heard of *droneless* colonies. To be sure, they will swarm, and it won't make a bit of difference about their having no drones. If you will examine the A B C book further you will notice that a queen rarely if ever mates with drones of her own. Nature has wisely arranged it so that she can not do it; therefore your bees are all right without any drones. If you had a whole apiary without drones, it might be a little different; but this, I believe, never happens.

WILL TRANSFERRING START SWARMING? OTHER QUESTIONS BY A B C SCHOLARS.

We began the season with eight strong colonies, six in box hives and two in Simplicities. We have transferred one, and have had four swarms up to date. Just as we got through transferring we looked up and saw a large swarm settled on a small apple-tree, a short distance from where we were transferring. We do not know whether the bees came from the hive transferred or from some other hive. We should like to know whether transferring will cause immediate swarming or not; or would they have swarmed anyhow in a short time? The swarm is doing better than the transferred colony. Our bees are all blacks, and we want to know if we can not run them for honey while the honey season lasts, and then get an Italian queen and Italianize them all. We are members of the A B C class.

We read Mr. Doolittle's article in regard to how to get honey into the sections. Now, that is our difficulty here. What would be the best plan to get honey put in sections in the Simplicity hives? How do you make dummies? I will also state that our bees wintered well in the open air, both in the Simplicity and in box hives, without any protection.

S. E. & I. E. PHILLIPS.

Fairburn, Ga., May 3, 1886.

I do not think, friend P., that transferring would be apt to induce swarming, but on the contrary. It might, however, induce the bees to abscond because they were displeased with so much changing and handling. I should suppose you could tell whether the swarm you mention came from your transferred hive or not, from the amount of bees remaining.—We do not use dummies. A chaff division-board would probably answer the same with the Simplicity hive.

A SWARM CHASING A TWO-WHEELED "SHAY."

A friend of the writer, while visiting in Maine, on the Androscoggin River, saw a swarm of bees on the wing, whose course seemed to be directly across a bridge over the above river, and just ahead of them was an old-style 2-wheeled "shay," containing an old gentleman and his wife. The vehicle was wide, and the back open, and the occupants were sitting so there was quite a space between them. My friend was quite interested to see if the bees would turn out for the chaise, as their course seemed to be directly for the open window, and just then they went through the open space between the couple, and out in front over the horse, and alighted on a tree near by. The lady was on the ground in an instant, with the greatest bewilderment at what had happened; but no harm was done, and the bees soon went into a hollow tree close at hand.

HOW A BEE-MAN RECOVERED HIS WINTER LOSS BY LETTING HIS BEES "SLIDE."

While visiting in my old home, Virden, Ill., about a year ago, a friend where I stopped lost some 18 swarms the winter before, and had but five left alive. We must call him a rather negligent bee-keeper, for he left his hives of empty comb standing on their summer stands all the spring. At swarming time, eight of those hives were occupied by absconding swarms. He saw two swarms come from a westerly direction and go into two of the hives, without alighting. The other ten hives were filled by his own bees, so he is sure none of the eight were from them, but must have come from a distance. **J. L. PEABODY.**

130 School St., Lowell, Mass.

Friend P., the facts you give us throw additional light on this matter of decoy hives.

IS IT ADVISABLE TO SELL BEES AT AUCTION?

I now have 63 colonies, and they are doing well. I think I shall increase to about 80, and then stop. My plan for strengthening weak colonies is the same as yours. I built up about ten, some of which were very weak. I go to a strong swarm and hunt the queen, and set her and the frame back, and then lift out a frame full of bees and brood, and give it to the weak colony. It works like a charm. If they quarreled any, a little smoking made them agree. Most of the time they seem glad to have company.

I think I shall sell off all of my bees this fall. I want to travel next summer for my health. Which would you advise me to do—sell them at a public sale, or try to sell them any way I can? I want to sell out, not because they don't pay, for they do pay, and pay well.

I bought three settings of Pekin duck-eggs, and I got 18 ducklings. They are four weeks old, and I have all 18 of them yet. This spring I raised seven young canaries. I tell you they are beauties. They are cute. I have 140 young chickens and 116 old ones. The two first hens I set, I gave them 30 eggs, and they brought out 28 chickens. I do all of my housework with the bees and ducks and birds and chickens. Don't you think I have enough to do?

MRS. MALINDA A. WILKINS.

Seneca, Kansas, June 8, 1886.

As to whether you should sell your bees at public sale or otherwise is a matter that somebody in your immediate locality can answer better than we can. I think perhaps if you advertise them in your local paper you might realize more from them than by public sale.—I should think you had done extremely well with your poultry business, with the other work you mention. We have been greatly delighted with a brood of Pekin ducks, but we have not succeeded as well as you have in raising them all.

HOW SHALL WE KEEP POLLEN OUT OF SECTIONS?

My bees want to put pollen into sections all the time when they work on white clover. They will put it in nearly every one when making worker comb, and some in drone comb. I use a honey-board over the frames. I wish C. C. Miller would tell us how he keeps it out, as he lives in a white-clover section. I believe the bees gather so much that they don't know what to do with it. I have known them to store it 12 inches above the brood. Bees are swarming, and work in the boxes quite well. The weather is very dry, and has been for some time. HENRY WILLSON.

Clinton, Ill., May 3, 1886.

As a rule, the use of separators discourages the queen from going into the sections, and, as a consequence, little if any brood is stored in them. I think your experience is a little unusual.

HOW TO CONSTRUCT A HONEY-ROOM IN THE GARRET, FOR BEES.

We have just had a flood, and I had to take my bees up stairs. I set them at the windows, and they did all right. I have your A B C book, and have looked through it thoroughly, and have failed to find out how to make a large bee-hive or a small room to put a hive of bees in, and take off the sides of the hive, and let them build comb to the sides of the room, hive, etc. You speak of something of the kind under the head of "Bees in Garrets," but how do you get into the room to cut the honey out? I should also feel obliged if you would give me a description of the hexagonal bee-hive on page 225, in A B C book. HARRY L. COOK.

Chattanooga, Tenn., May, 1886.

I do not know how to direct the making of a bee-garret. The results of investigations, wherever I have found such garrets, have been so unfavorable that I do not believe it is best to spend much time or money on the matter. The Hexagonal bee-hive you allude to was the project of a friend who wanted to see what he could do. The hive cost him something like $50.00, and I believe it gave him several good yields of honey. We had an engraving of it made, and it was described in GLEANINGS for Feb., 1882, page 62. It is interesting as a curiosity, but I don't believe any one wants many hives of that kind.

DO BEES GATHER HONEY FROM HARD MAPLE?

On page 658, October No., last year, friend Doolittle says that, according to his observations, bees gather very little honey from hard maple, but plenty of pollen. Now, according to my experience the hard maple yields honey abundantly; in fact, I think it is equal to fruit-bloom for honey, and the honey is of better quality. But, of course, as the weather is usually unfavorable during the maple bloom there is comparatively little saved by the bees. I have never experimented as carefully as friend Doolittle; but this I know: We have no willow in bloom when the sugar-tree is in bloom, nor is there any other source where bees gather honey at that time, except dandelion, which did not bloom this year. So while the sugar-trees were in bloom the bees worked with a vim equal to fruit-bloom, and stored considerable honey, although the weather was very unfavorable most of the time during the two weeks they were in bloom, and the honey was of excellent quality.

We can not always compare our localities with others; as, for instance, I see reports from some localities that bees make considerable honey from the goldenrod. Now, two years ago I had a field of eight acres covered with it, and I never saw a bee on a goldenrod blossom in my life.

The season in this locality was a very poor one for honey last year. A great many of our bee-keepers did not get any honey at all. My report is as follows: 30 lbs. of comb honey per colony and two swarms. My best colony gave 50 lbs.

Farmington, W. Va. L. H. WILCOX.

I am inclined to agree with you, friend W., that the hard maple does at times yield considerable honey. Two or three years ago we had a season when the bees were filling the hives with new honey. So much of it was brought in, that, when we turned the combs over to look at the brood, the honey would run out on our clothing. It had the taste, somewhat, of maple syrup; and as the hard maples were just roaring with bees for many days, I decided the honey-flow came from them. Did you taste the honey, and see what it was like?

MRS. AXTELL ON FORMING NUCLEI.

The way I like best to make nuclei is this: Go to my blackest, or poorest and smallest colonies; take out all the combs and adhering bees, and carry to a new hive on a new location, two of which combs I set in the hive; then brush off the bees from the remaining combs into the hive. Now we know we have the queen, and enough of the bees will remain to care for the queen and brood well (as only a strong nucleus pays). Now carry back the other two or three combs to the old stand, and enough bees will return to care for them. If a colony is strong enough, three or more nuclei may be made of the one weak colony. I like to pick out my darkest hybrids or poorest-queened colonies, because I do not wish to raise drones from them. It is the easiest way to get them requeened. MRS. L. C. AXTELL.

Roseville, Ill., May 26, 1886.

HOW TO COOK CARP.

My husband has been getting some carp from a neighbor's pond, and they are almost as bony as the eastern "red horse," or suckers, and taste very much like them. A good many object to buying them, on account of the bones. As I like the flavor of them, I have tried various ways of cooking them. The best way for us is to bake them. We kill, and clean them thoroughly the day they are caught. They sometimes need washing six or seven times in clear water. Then let them stand in clear water all night. Wash them once again in the morning, and then cut off tails and fins, and pack them heads and tails; that is, as close as I can get them, and about two deep, in a baking-dish of some kind. I use a long dripper. As I pack I sprinkle a little salt and pepper inside them, then put in water until just even with the top of the fish; and if liked, a little nice meat-drippings or butter is added; then bake for two hours, or longer if desired. I do not add any more water, preferring to let them be about dry when done. When so prepared, the bones are nearly all as soft as those are in canned salmon, and they are much relished. If any are left I warm them up in hot lard and a little extra salt.

Los Alamos, Cal. MRS. J. HILTON.

DOES CHANGING THE INTERIOR OF THE HIVE PREVENT SWARMING?

I am a beginner in keeping bees, and I should like to run them without increase. I have been wondering if I could not do it in this way: After the swarm issues, put all the frames containing brood in lower story, with enough frames of foundation to fill up the lower story. Then put the frames containing honey in upper story, with frames of foundation to fill out the story. I could put a frame of foundation between frames of brood to change the interior of the hive, so that the bees would hardly know it was their old hive. After the upper story is filled, extract.

H. M. PARKER.

Plymouth, Richland Co., O., May 25, 1886.

Friend P., the plan you suggest will be nearly equivalent to reversing the brood-combs, as mentioned on another page by friend Alley; and my experience is, that sometimes it works, and, again, it does not work.

HONEY-DEW, ETC.

I sold 36 stands of bees last year and 3 this spring, and I have 22 on hand at this time, and will not sell any more until swarming is over. I lost none this winter. Bees have been doing well until the last two weeks, when we had a heavy frost that killed all the bloom; but they are coming out again. Last year, and year before last, I had swarms out by the 22d of March. They will be late this spring. They will surely go to swarming in a few days. I have not made any divisions yet, and I don't expect to.

When I get time I will write you a letter on the production of honey-dew, as I am satisfied that I have discovered it, and I should like for you to let me know if it has ever been satisfactorily settled as to what produces it.

J. A. ISAACKS.

Brownwood, Tex., May 1, 1886.

Friend I., I believe it has pretty generally been agreed upon, that honey-dew is the product of aphides, or some sort of insects. The idea that it falls from the air or clouds is too improbable to receive credence, without a very great amount of positive proof. If you have any thing new to offer on the subject, we shall be glad to receive it.

HOW SHALL WE SHIP OUR HONEY IN THE QUANTITY?

I do most terribly hate to peddle, so I offered one of our merchants here my whole prospective crop of extracted honey from 40 hives for 8 cts. per lb., and take it all in trade out of his store, he finding a market for it among his acquaintances in New York. He told me to-day, that after several days to think about it, if I would put it in tin pails of about 5 lbs., so that he could crate it and ship it to New York he would accept my proposition. He is hardly willing to take it in barrels. I can retail it from 10 to 12½ cts., a limited quantity, but I do so much like to dispose of a crop in bulk. I want to see what can be done.

FRANCIS TRUEBLOOD.

Archer, Fla., May 21, 1886.

CARNIOLANS IN CANADA.

I have to smile a little at your concluding remarks about Carniolan bees, on page 424. The bees produced by the Carniolan queen I got from J. H. Morrison last September are perfect hybrids in every respect, temper not excepted. Now, how are we to tell when we have pure Carniolans? The old-fashioned German bees have a grayish appearance, especially when they are young. Can it be possible that we are being imposed upon, and are getting back our old race of bees? I am feeling just a little sorry that I ever got any other race mixed with our Italians. Apple-trees are in full bloom yet, but the weather is so cool there is no honey secreted. The Syrians are terribly cross; but when we are opening hives we can soon tell where there is Italian blood.

ILA MICHENER.

Low Banks, Ontario, May 29, 1886.

CARNIOLANS AS WORKERS.

I am quite surprised at your article in June 15th No., in reference to Carniolan bees as workers. I have had Italians, Syrians, Cyprians, blacks, and hybrids, but I have never yet seen any honey-gatherers equal to the Carniolans I now have. My experience with the race as to gentleness is, that when the queens have mated with Carniolan drones we have the gentlest bees; but whether mated with Syrian, Italian, or black drones, the worker progeny is still gentle and lovely. I believe Dr. Tinker got a queen from me, mated with a Syrian drone; would he be kind enough to report quality of workers? I have never had any other queens so prolific. I see no trait about them but superiority in every way over any other race I know of. I think it is doubted that the colony you reported on is Carniolan. Didn't you report in GLEANINGS, soon after getting them, that you saw no difference between the workers of your queen marked "best," and Italians? Carniolans certainly have no yellow bands.

Oxford, Pa. S. W. MORRISON, M. D.

Friend, M., we were a little surprised to find a few worker-bees from our Carniolan queen yellow-banded; but they came from Frank Benton direct, and he would doubtless send us as good as he had, expecting, of course, we would report. Furthermore, if I am not mistaken, both Mr. Benton and other writers have admitted that a part of these bees are yellow-banded. When I saw this admission I was considerably inclined to feel vexed. Suppose we have the matter decided before we go any further, as to whether Carniolan workers should be yellow-banded or not. If they are not a pure breed at all, will it not be best to drop them right where they are? See letter above.

HOW EASY IT IS TO BE MISTAKEN.

A great many times friends write us that they ordered so and so, and yet they received something they didn't order at all. Now, where no copy of the order is kept, people are usually so positive the mistake is not theirs, I have been obliged to give the clerks particular directions to close up every letter of explanation by saying, "We can return you your letter, should you not think we are correct in the matter, if you so desire." Unless the above is added, there is pretty sure to be hard feelings, and sometimes hard words. The following kind letter illustrates the point:

You can not imagine how good I felt when I received back from you my letter of May 7th, 1886. After waiting, telegraphing, telephoning, and at last paying $1.30 for freight for the sections, it turns out after all that *I* am to blame for all of it. To say that I was vexed would be putting it in a very mild way. The reason I feel good *now* is because I did not scold you for all this trouble made by myself and for myself. Now, in future I will try to be more careful about what I say. But suppose *you* had made the mistake, as I firmly believed you had until you returned my letter, what would have been the result? My opinion is, that you would have made it all right. I have all the supplies that I need for this season; but when I need any thing in your line I will order. J. F. MICHAEL.

German, Darke Co., O., June 21, 1886.

I am sure, friend Michael, we are very much obliged indeed for your kind concluding words, and we will try hard to deserve them.

Moral.—When you make an order, always keep a copy, so as to be sure you are not mistaken when you feel like complaining that you didn't get what you ordered.

WHEN TO TAKE OFF HONEY.

I have one of your A B C books, and am pleased with it. Can you inform me where I can find a good market for section honey, and what it is worth per pound? I have fifty colonies of Italians, and they produce a very good yield, but honey is worth only, through this State, 10 cts. per lb. You mention in your book, that you always get 18 cts. for yours. Be kind enough to lend me a helping hand in this direction. How late in the season do you take honey? My plan is to remove from upper story, any time from the first of May to the middle of September, but never take any from the brood-chamber. Please give me your ideas on the subject. You don't mention this in your book. R. H. CAMPBELL.

Madison, Ga., June 19, 1886.

Why, friend C., we continue to take off honey as long as any comes; that is, I should take off every bit in the sections; and if they then lacked in the brood-chamber, when it came time to prepare them for winter I would feed. If you want your honey extra nice, take it off as fast as the sections are capped over. Every day they remain over the bees after this, spoils their appearance.

REPORTS ENCOURAGING.

"BEES DOING FIRST RATE."

BEES are doing first rate here, and white clover is in full bloom. Cultivated raspberries, blackberries, and tulip-trees, furnish lots of honey also. There is only one large tulip-tree within easy reach, but the bees carry in honey from that one an hour or two every morning. ALLEN LATHAM.

Lancaster, Mass., June 19, 1886.

NEBRASKA.

Bees are doing finely. We hope to get some surplus soon. We are in the midst of strawberry picking. We have the finest that go to our market.

Plattsmouth, Neb., June 9, 1886. W. J. HESSER.

WILL QUADRUPLE THE STOCK.

My wife is excited over her success with bees. Last year she tripled, and this year she will quadruple her stock (from appearances). They bred all winter; first swarm, May 22d; second, from same colony, June 5th, and will swarm again all round.

SAMUEL T. MALEHORN.

Denmark, Oregon, June 10, 1886.

HONEY NEVER BEFORE COMING IN SO FAST.

Bees are doing first rate now, but I am afraid of dry weather setting in that will cut off the clover. There is an abundance of it. I have taken 40 lbs. of comb honey from some of my hives, and there will be plenty more in a few days. I never saw them make honey so fast before in my life.

Millersburg, O., June 7, 1886. JACOB ETTER.

BEES AT "WORK IN SECTIONS STRONG."

Bees are doing remarkably well so far this season. We are having an excellent clover-bloom, and bees are at present gathering more honey from it than I remember of ever seeing before. They are at work in the sections strong, and are just beginning to swarm. I had two swarms to-day.

Williamsville, N. Y., June 22, 1886. E. C. LONG.

A GOOD REPORT FROM ONE OF OUR DOLLAR QUEENS, AND ONE, TOO, THAT DOES NOT SWARM.

I bought a dollar queen of you 4 years ago, and introduced her to a colony of blacks. In a short time I had a colony of pure Italians, and they are beauties too. They have given 87, 103, 108, and 97 pounds of honey each year respectively. What I want to know is, why they have never swarmed or even built a queen-cell. I know it is the same queen, for I clipped her wing a few days after introducing her, and saw her last on the 11th inst. Is it not strange that they do not swarm? I am very proud of her. C. A. LEWIS.

Peachville, Pa., June 14, 1886.

100 LBS. OF HONEY IN 5 DAYS FROM ONE SWARM; OWES SUCCESS TO THE A B C BOOK.

I have not written any thing for GLEANINGS for three years. Your reply at the end of my article was to let you hear from me again. This fall I will send you another report. I have made great strides in the art since I commenced, 7 years ago. I have had great success in getting honey, but not in wintering. Last year, 8 swarms averaged 200 lbs. of extracted honey apiece. One new prime swarm, hived on 24 empty combs, gathered over 100 lbs. in 5 days. I owe much of my success to what I learned in the A B C book. C. S. ADAMS.

Williamson, N. Y., June 20, 1886.

CLOVER TWO WEEKS EARLIER; THE SWARMING MANIA RAGING.

Bees are doing well. White clover commenced blooming May 10th, two weeks earlier than usual, and has furnished a good supply of nectar. Basswood is opening up now. Trees are full of buds; and if the weather is suitable we shall have a good honey-crop, which will be the first within three years. Our woods are full of runaway swarms. Persons keeping a few bees, and not paying close attention, have lost half of their swarms that have come out this season. We have lost three. Two first swarms came out and went to the woods without settling. One was followed three-fourths of a mile. There is something very singular about the swarming this year. We have had one swarm to come out five times. It was hived on brood and foundation. It would stay in the hive two or three days, work out some of the foundation, and then swarm out again. Others will stay in the hive a day, and not do any thing, and swarm again. My hives are well shaded, and the best of care given in hiving. Some swarms destroy all the larvæ given them, if rather young. J. NEBEL & SON.

High Hill, Mo., June 19, 1886.

OUR OWN APIARY.

DOOLITTLE'S PLAN OF FORMING NUCLEI, AS TRIED AT OUR APIARY.

EVER since Mr. Doolittle gave his plan of forming nuclei (p. 304, last year, and p. 401, current volume), I have had a great curiosity to know whether it would work successfully here. As our apiarists have been practicing artificial swarming, I told one of the boys to try Doolittle's plan, and I determined to put it severely to the test. I accordingly instructed him to take six different frames, with adhering bees, from as many different colonies, being careful that the queen was not on any of said frames. These in rotation, as fast as taken from the hives, were shaken over the tunnel, precipitating the bees into one of our 1½-lb. shipping wire-cloth cages. An effort was made to shake all the ragged-winged old bees into the cage, taking advantage of the fact that young bees adhere more closely to the combs. When the cage was filled it contained about a quarter of a pound of bees from six different colonies, making, by actual weight, a pound and a half of bees, a large part of which were old ragged-winged fellows. Among these were dropped a queen from a seventh colony, so that we had seven colonies represented in this cage of bees. We would naturally expect that these bees would be apt to quarrel—at any rate, kill the queen. According to directions, the bees were jumbled up considerably, and then placed in a cool dark place over night, to become acquainted with each other. Next morning they were put in a hive where previously had been put a frame of unsealed larvæ and a frame of honey, and two or three empty combs. I watched the bees narrowly, to see whether any would return to their old stands. At noon of the same day, on examining the hive I concluded that most of the bees were still there; but I failed to see many of the old ragged-winged bees. I then concluded that they had gone to their old locations.

At 7 P.M., on looking into said colony, I was gratified and surprised to find that those same old ragged-winged bees were all there, they having evidently at noon been out foraging, and at night were at home. Yes, those ragged-winged old fellows were scattered all through the hive, and the queen was in the center of a ring of bees, unharmed.

Now, if, by the ordinary way, these six frames of bees had been put directly together in some one hive, the old ragged wings would all have returned to their old locations. Isn't that so, friend D.? Besides, if the queen had been dropped right among them, as she was in the cage, she probably would have been killed. I don't know whether or not friend Doolittle has tried forming an artificial swarm from so many different colonies, but I felt sure that if it would stand this test, his plan ought to work successfully, as ordinarily practiced by him. I am aware that it involves considerable labor; but the point is, if I understand correctly, to make *all* the bees stay at their new location, and perform, as nearly as possible, the functions of a natural swarm.

Of course, I would not say that, because this one instance has proved successful, therefore the plan will always work. We shall try it again, and will report later. Well, suppose it will work successfully every time, will the consequent labor involved pay you for your trouble? This you will have to settle for yourselves. Mr. Doolittle has practiced it for a couple of years back, and I believe he still considers it the most economical way of forming nuclei or strengthening weak colonies. Mr. Fowls, of Oberlin, O., said he had met with good success by it, and thought it one of the valuable "kinks" to the trade.

WHAT FUEL IS BEST FOR SMOKERS? THE FUEL THAT WE NOW PREFER AT THE HOME OF THE HONEY-BEES.

Among some of the practical ideas in Mr. Heddon's "Success in Bee Culture" we find planer shavings mentioned by "my friend," and recommended by Mr. Heddon as being the best fuel for smokers. The boys tried this fuel, prepared in the way described; but while they met with fair success, the shavings burned out too quickly, and sometimes went out altogether. No doubt, with the Bingham smoker, this fuel will do all that is claimed by Mr. Heddon; but with the Clark, the *modus operandi*, by reason of the difference in draft, has to be varied somewhat.

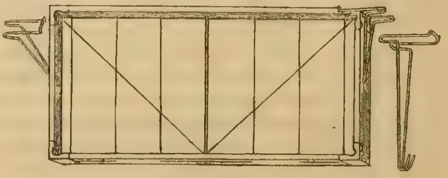
HOW TO MAKE THE CLARK SMOKER RUN FROM FOUR TO SEVEN HOURS IN THE APIARY WITHOUT REFILLING.

One of the boys then substituted, in place of the shavings, fine basswood sawdust; and, strange as it may seem, it gave excellent satisfaction, burning for a great length of time, and sending out a volume of smoke. The manner of filling is simply to put a few live coals over the grate (holding the nozzle downward), and then filling the fire-box level full with the fine basswood sawdust, such as comes from sawing sections. The smoker, as thus loaded, will last from four to seven hours, depending upon the amount of wind blowing. If the air is still, and the smoker is filled just right, it may be expected to run for a long time without refilling. We much prefer basswood sawdust to pine, as the latter is too apt to fill up the tube with tar. I suppose any hardwood sawdust will answer as well as the basswood.

The secret of the sawdust lasting so long rests in the fact that sawdust will smoulder for a great length of time, without going out. When our honey-house caught fire, something over a dozen years ago, we discovered that the fire originated from the sawdust packing holding fire for a whole day and night, and I believe other fires have been traceable to the same cause.

THE SIMPLICITY REVERSIBLE FRAMES.

We have tried a number of these frames, with excellent satisfaction. They reverse surprisingly easy, even when covered with propolis; and for general handling, the boys like them much better than the knife-edge metal corners. To hold a frame filled with honey by these metal corners, is sometimes a little uncomfortable to the fingers. These reversible wire corners are easy on the fingers, and at the same time possess all the good features of the old metal corners. For the benefit of our readers who may wish to see it, I here reproduce it.



THE SIMPLICITY REVERSIBLE FRAME.

The cut will, I think, make the principle plain. To reverse, the corner is slipped off, and is then revolved to the other corner, where it is slipped into place.

I must say, from my experience I am greatly pleased with the reversing principle. We have secured by it some as fine combs as I ever saw, the frames being filled out solid from bottom-bar to top-bar. Even with wired frames the bees will scarcely ever build the comb plump against the bottom-bar. Near the lower end of the comb the bees are apt to gnaw around the wires. Frames of this description have been reversed, and the combs then completely filled out in a day or so. If we continue to like this reversing principle, we shall use it entirely in the apiary. We already have quite a number in use. From the experience I have had I do not think I should like to reverse the whole hive; i. e., all the frames at once. On examining into a number of hives, I saw some combs which needed reversing, when, to reverse others in the same hive, would only result in harm—at least, so it seems to me. To reverse the frames singly is not a very long operation.

I should still advise the friends who have had no experience with them not to put too many reversing frames in the apiary at once. Although many like them at present, we may all decide adversely to them in time.

CARNIOLANS STILL LAGGING.

These bees are not doing much better. Although by all odds the strongest colony in the apiary, they have no more honey in their hive than ordinary Italian nuclei. Two of the frames of foundation which I told you about last issue have not yet been pulled out. Such a strong colony, in the space of two weeks, during the honey-flow, ought to have had the fdn. drawn out long before this. I will say to Dr. Morrison, that the bees in question are from a Carniolan queen which Benton called "very fine." There are only a few Italians among them. As we have been expecting them to swarm, we have attached to the entrance one of the Alley traps, both to catch the queen in case the swarm issues, and to catch all the drones, as we do not wish to have any of their blood in our apiary.

This morning the apiarist found a young virgin queen trying to pass the trap attached to the Carniolan swarm. She made repeated attempts to get through, but without success. The apiarist then took her away after the bees had balled her. This shows that even young queens can not pass the zinc, so that there is no doubt, when the Carniolan queen comes forth with the swarm, she will find that she is "left."

HURRAH FOR THE ALLEY TRAP.

Later.—This afternoon, at a quarter before four, while in the apiary I saw a big swarm in the air. Going directly to the Carniolan swarm I found the bees pouring out of this hive through the trap. Yes, sure enough, there was the queen in the upper apartment, where she had passed through the cone when she found herself unable to pass the perforated metal. The bees circled around in the air for about five minutes, when, finding their queen absent, they poured back into the hive through the trap amazingly quick. I had nothing to do but to watch them. It works about the same as clipping the queen's wings, with the exception that you do not have to hunt for the queen. The trap is automatic, and is, no doubt, a great saying of labor. If I had wished to put the swarm in another hive, all I should have had to do would have been to detach the trap from the hive and suspend it in the air. The bees would soon have clustered around their caged queen, and I could have put them wherever I pleased.

I would say, that we do not ordinarily allow swarming; but I had made the conditions favorable for the issue of this swarm for the express purpose of testing the trap. This invention of Mr. Alley's will prove a great boon to those who have apiaries located in different places, and where they have to hire expensive help to take care of the swarming. ERNEST.

I am the light of the world.—JOHN 9. 5.

WE have, at this date, June 29, 5623 subscribers. We are also filling all orders almost the day they are received. If any one has been missed, let us know and we will fix it instantly.

MR. THOMAS HORN AND HIS BUSINESS.

WITH the number of complaints we are having, it is no longer possible for us to keep silent, although it is my opinion that Mr. Horn means to make every thing satisfactory with his customers, when he gets through with his great rush of orders. The only thing we can blame him for is, that he does not return the money promptly when his customers write that they prefer it instead of waiting longer. We wrote him that he must either return the money or make some explanation to his patrons, that we could publish, before this issue went out. In reply to this we get the following telegram:

> Can not attend to mail myself—orders are positive to return if not filled. If not, answer. Please write again letter to-day. THOS. HORN.

SECRET SOCIETIES.

WITHOUT presuming to dictate, I feel it nevertheless my duty to say that, when my advice is asked, I do not hesitate to reply that I can not see any need at present of secret societies of any kind. Especially does it seem to me that one who professes to be a follower of the Lord Jesus Christ has no need of secrecy in this way. Jesus taught openly. I am well aware that many professors of religion are members of secret societies of different kinds. I know, also, that our young people, many of them, are members of secret societies that claim to have as their end and aim the furthering of the kingdom of God; but for all that, I feel a little sad and a little afraid when I hear that any young friend of mine has become a member of any of these. Our prayer-meetings are not only open and free to all, but every true Christian is always glad to welcome the presence of any human being, no matter what the color, sex, or social condition. If we are seeking first the kingdom of God and his righteousness, is there any need of secrecy anywhere in this wide universe? Shall we not so live that we shall never be afraid to have the all-seeing Eye look down into the innermost depths of our own hearts? and shall we not also so live that we need never fear to have human eyes look into the business of our lives, and even scan closely the work of our hands? "In secret have I said nothing," are the words of our Savior.

HAND-BOOKS ON RURAL INDUSTRIES, AND WHAT THEY SHOULD COST.

One of the things to rejoice about during this nineteenth century is the fact that almost every thing is taught in books; that is, a whole book is written in regard to potato culture, and another on cranberry culture, a third one on broom-corn, etc. Not only have we *poultry*-books, but we have a book written specially in regard to the *Light Brahmas;* and these text-books are a wonderful help in their respective lines of business. But what I want to protest against in this brief notice is, the fashion of advertising a "book," charging 25 or 50 cts. for it, and sending, in return, a brief *pamphlet* that should be sold for a nickel or a dime. Three books are now being advertised extensively in the agricultural papers, on celery culture. One is 25 cts.; the other two, 50 cts. each. Now, a book on celery culture is very much needed, and I have sent for every thing that has come out, just as soon as I saw it advertised. The 25-cent one is by J. N. Stearns, Kalamazoo, Mich. The title is, "Celery Culture." Said book has a cover 4×6 inches. Inside it are six leaves, 4×6 inches. One of the 12 pages is occupied by an advertisement of something foreign to the subject. The type is large and widely displayed. Every thing in the book would not make a single page of GLEANINGS, and yet it is advertised and sold for 25 cts. The other two, at 50 cts. each, are entitled respectively, "Kalamazoo Celery," and, "How to Grow Celery." One contains 23 pages; the other, 30; size of the books, 4½×7 inches. The matter is tolerably fair, what there is of it; but there is not a single illustration to explain the operations of celery culture, in any one of the books. Ten cents would, in my opinion, be an ample price for them. Of course, these books will be short-lived, and the sale of them limited. Instead of being treasured up as something of value, they will be torn up or lost, or go into the waste-paper basket in a week or two. It is true, they may be worth all they cost to many of the purchasers; but to my notion it is not *right*, and it is not *fair*. If the advertiser should, in his advertisement, say how large his "book" is, and tell the number of pages it contains, he would find hardly a purchaser. Large books are not needed on many of these subjects; but why can't we have something like a uniform price, even on industrial pamphlets? And why not call them so, instead of calling them *books?* Perhaps you urge that it would not pay; but I reply, it *will* pay a fair and reasonable profit to get out a good book, full of pictures, illustrating the subject, and sell it so as to furnish the purchaser, say a good-sized page (the size of GLEANINGS, for instance), at the rate of a cent a page, or not to exceed that price. Industrial hand-books can be furnished at the above figures, so as to pay reasonably well, I know, because I have tried it.

BOOK-REVIEW DEPARTMENT.

DOES IT TAKE TWENTY POUNDS OF HONEY TO MAKE ONE POUND OF WAX?

MR. P. L. VIALLON, Bayou Goula, La., criticises somewhat my conclusion in this department of May 15, as regards the original cost of wax, as adduced from the consequent consumption of honey. As he mentions some of our time-honored experimenters and writers who have given the matter some attention, I insert it below, that we may together consider what he has to say:

> *Mr. Ernest Root:*—In your book-review of May 15, you say: "From the fact that McLain's estimate of the cost of wax is backed by former experiments some years ago, it would seem that 20 lbs. of honey to 1 lb. of wax is very nearly correct." Don't you think that you are rather premature in coming to this conclusion, for McLain's estimate, based only on opinion, as far as I can see, is given as such? You also refer to the paper read by me at the convention in New Orleans, and say that I "gave as my opinion," etc. I think that it would have been better to say that I gave my modus operandi and the results of my experiments, etc. Now, as you have put me in evidence showing the great difference between Prof. McLain's opinion and the result of my experiments, which will, no doubt, cause critical reflections, and wishing to verify my experiments to a certain extent, I would call your attention to the experiments of Berlepsch and others in Europe; and among our prominent bee-keepers here, Mr. C. Dadant says about 10 lbs. of honey is required, basing his opinion on the amount of grain required to produce 1 lb. of fat in animals. If you read friend Doolittle's article in the *C. B. J.*, May 26, you will see that he says that it takes less than 5 lbs. of honey to make 1 lb. of wax, when bees are not confined, and have access to plenty of pollen and water from the fields, etc. If I am not mistaken, Mr. J. Heddon's estimate is not far from the above.
> P. L. VIALLON.
>
> Bayou Goula, La., June 3, 1886.

I am very glad, friend Viallon, that you have spoken so freely, if I do seem to be "waxed pretty bad;" but as nearly as I can discover, McLain *is* backed by former experimenters, and it was the most natural thing in the world to conclude that the old estimate was nearly correct. You say I ought to have given the results of your *experiments*. If you will look again, page 392, you will see that I did put it as the results of your experiments; namely, 7 lbs. of honey to 1 lb. of wax. From the reading of McLain's report I had supposed that the professor had arrived at his conclusions from experiments; quoting from his report we find the following: "Estimates can easily be furnished to prove that the production of every pound of wax costs the bee-keeper ten times the sum realized from its sale." I take it from this that he had made some experiments as regards the cost of wax.

On consulting several of the bee-books I find it seems to be presupposed that it takes from 15 to 25 lbs. of honey to make one pound of wax. Whether these data were obtained from actual experiment of the authors, I am not prepared to say. If the results of your experiments, friend Viallon, are correct, then these books need revising on this point.

As we have here on file all the bee-journals since started, I took a little search in some of them. Turning back to the *American Bee-Journal* of 1861, Vol. I., page 88, we find there recorded the experiments of Gundelach and of Baron Berlepsch. In the second paragraph we find: "Gundelach made some minute and careful experiments, the details of which are given in the 'Natural History of the Honey-Bee,' and the results showed that about 20 lbs. of honey were used by the bees in producing a pound of wax." Again, in the third paragraph occurs the following: "A similar experment" (referring to the one just quoted) "with like results was made by the Baron of Berlepsch. In a subsequent experiment he allowed the bees free access to pollen, and ascertained that, in such case, 13 lbs. of honey (exclusive of the pollen consumed) sufficed to produce a pound of wax." The above are verbatim quotations. Remember we are not talking about the amount of *pollen* and honey required for a pound of wax, but *honey* alone. The pollen in the last experiment probably accounts largely for the difference in results.

In the same article, further on, we find: "Again, Count Stosch, taking the second experiment of the Baron of Berlepsch as the basis of his estimate, thinks due allowance should be made for the time spent in comb-building by the bees, and which, if devoted to honey-gathering, would have enabled them to store up 20 lbs. Hence, he concludes that, with the actual consumption and the necessary allowance for time and labor, the cost of a pound of wax is fully equivalent to 30 lbs. of honey."

If I am correct, the foregoing extracts refer to the German friends Mr. Viallon has in mind, but I do not see that the "results" of their experiments particularly favor him, but rather verify what Prof. McLain has said. If our German experimenters have made any more recent experiments, the results of which are radically different, I should be glad to be informed of it.

Mr. Dadant is quoted as saying 10 lbs. of honey only are required for one pound of wax. As he obtains this estimate from the quantity of grain required to make a pound of fat, it seems to me this estimate bears the force of only an assumption. The fat of animals and the wax of bees may be similar, but I do not see how the proportion can hold true, if we reason that corn is to fat as honey is to wax, which, when sifted down, amounts to about that. It may approach the truth, but not accurately, or, at least, so it seems to me.

Mr. Doolittle is mentioned as saying in the *C. B. J.*, page 166, that only 5 pounds of honey is required for 1 pound of wax; but, observe, he gives it as his *opinion*. He states the reasons for his belief, but using Viallon's terms, not the *modus operandi* or the results of his experiments, strictly speaking.

Now, friends, while I confess I had just a "leetle" desire to talk back to friend Viallon, it is not my purpose in making these extracts and allusions from some of our prominent writers to show by their use that the results of Viallon's experiments were incorrect, or that Doolittle was wrong in his belief; but to show from various sources, so far as I was able, the result of previous investigation upon the one point of the *original* cost of wax. Indeed, I would regard it as presumption to take issue with some of the old writers who have long been in the field. My object is to call forth a settlement of this "wax question," if possible, as proven by a series of careful and impartial experiments of the present time. Wax has now become one of the staple articles of commerce, and I regard it highly important that bee-keepers know pretty nearly what it will cost them to produce it when honey is of slow sale. If it can be produced at a cost below the market prices, then surely we ought to know it. Several have inquired whether they could produce and sell wax at a profit. Perhaps with the knowledge of what has been done we can prove that the original cost of wax is considerably lower than the old estimate. Strange as it may seem, I sincerely hope it may be demonstrated, for it would develop a new income for the bee-keeper; and it is quite probable that, as Mr. Doolittle suggests, when the bees have access to open air we may arrive at quite different results.

ERNEST.

BEE - KEEPER'S GUIDE;
Or, MANUAL OF THE APIARY.
12,000 SOLD SINCE 1876.
13th THOUSAND JUST OUT!
10th THOUSAND SOLD IN JUST FOUR MONTHS!
4000 Sold Since May, 1883.

More than 50 pages, and more than 50 fine illustrations were added in the 8th edition. The whole work has been thoroughly revised, and contains the very latest in respect to bee-keeping. It is certainly the fullest and most scientific work treating of bees in the World. Price, by mail, **$1.25.** Liberal discount to dealers and to clubs.

A. J. COOK, Author and Publisher,
13-23 Agricultural College, Mich.

W. Z. HUTCHINSON,
ROGERSVILLE, GENESEE CO., MICH.,

is rearing Italian queens for sale again this season, and can furnish them by mail, safe arrival guaranteed, as follows: Single queen, $1.00; six queens for $5.00; twelve or more, 75 cts. each. Tested queens, $2.00 each. Make money orders payable at Flint, Mich. Send for price list of bees (full colonies, or by the pound). Given foundation, white-poplar sections, hives, cases, feeders, empty combs, etc. 13tfd

LEWIS V-GROOVE
ONE-PIECE SECTIONS

WE WILL SELL

Chaff hives complete, with lower frames, for $2.50; in flat, $1.50. A liberal discount by the quantity. Simplicity hives, Section Boxes, Comb Fdn., and other Supplies, at a great reduction. We have new machinery, and an enlarged shop. **Italian Bees and Queens.** Send for Price List. 23 22db

A. F. STAUFFER & CO., Sterling, Ills.

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ad's intended for this department must not exceed 5 lines, and you must SAY you want your ad. in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates.

WANTED.—To exchange 20,000 strawberry-plants, Crescent Seedling, Cumberland Triumph, Sharpless, and Glendale, 75 cts. per 100; $4.00 per 1000, for bees, foundation, or improved poultry.
10tfdb W. J. HESSER, Plattsmouth, Neb.

WANTED.—To exchange for extracted honey, cash or offers, 15,000 pot-grown strawberry-plants of the best varieties; also game cocks and Jersey Red pigs. Can give best reference. 12-13d
Address GEO. M. WERTZ,
Johnstown, Cambria Co., Pa.

WANTED.—To buy for cash, from 100 to 500 pieces, either pine, poplar, or basswood, 7 feet long, 3½ inches wide, 1⅜ inches thick, planed all over, with a rabbet taken from one corner 1¼ inches by ½ inch. Who can furnish them? 12-13d
THOS. W. CROACHER, New Bedford, Mass.

WANTED.—To sell, after June 1st, 50 3-frame L. size nucleus colonies of hybrid bees, with queens, for $3.50 each, delivered at Plattsmouth, Neb., or I will exchange for young stock, cattle or horses, or apiarian supplies.
12tfdb J. M. YOUNG, Rock Bluff, Cass Co., Neb.

WANTED.—To sell or exchange a farm, 160 acres; good buildings, good soil, good title. All under fence. For sale at a fair price. Address 12tfdb
W. B. BROWN, Spirit Lake, Dickinson Co., Ia.

WANTED.—To exchange Gale plow, square harrow, subsoil plow, double lead harness, riding-saddle, horse-clippers; also a Stevens 44 rifle and 12-gauge shot-gun combined, for Barnes saw, hives in flat, or offers. Goods shipped from Philadelphia, Pa.
12-13d H. M. HIESPELL, Paola, Fla.

WANTED.—To exchange five full-blood Scotch shepherd pups for $5.00 in cash each, or six warranted Italian queens. Stock warranted full, and satisfaction guaranteed. Address
13d T. J. PENICK, Williston, Fayette Co., Tenn.

WANTED.—To exchange Italian bees in three-frame nucleus with queen, at $3.50 each, for fdn., brood size, 8x16½. Also young queens at $1.00 each. 13-14d M. ISBELL, Norwich, N. Y.

WANTED.—To exchange Italian and hybrid bees for pure beeswax comb fdn., Wyandotte, Brown Leghorn, and Plymouth Rock chickens, or offers.
A. E. WOODWARD, Groom's Corners,
13d Saratoga Co., N. Y.

FOR SALE or exchange, White English Rabbits, choice stock very low, now; also P. ducks and poultry cuts for sale cheap.
13-14d O. L. COVER, Covington, Ohio.

WANTED.—To exchange bees in Root's Simp. or chaff hives, or a saw-table with $7.00 mandrel, suitable for power, for a Barnes foot-power circular saw, or will sell cheap for cash.
13-16db M. LUDTMAN, Hannibal, Monroe Co., Ohio.

FOR SALE.—Italian Bees and brood. Queens bred from imported mothers. Or I will exchange for supplies at a bargain.
13tfdb C. F. UHL, Millersburg, Ohio.

WANTED.—To exchange even Rose-comb Brown Leghorn cockerels, April hatch, standard birds, for Italian queens or comb foundation. Price $1.00 here. 13d W. M. JANES, Paris, Tenn.

LOOK HERE! To any one wishing to purchase nice Italian bees I will furnish them, during the month of July, for 50 cts. per pound. Tested queens, $1.00 each; all queens reared from cells built under the swarming impulse. In all cases, cash must accompany order.
13-14 A. G. BRUSH, Susquehanna, Pa.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I will sell 30 hybrid queens in July, at 25 cts. each. Insure safe delivery, and that queens are layers.
JOHN S. SARGENT, Hutton, Coles Co., Ill.

I can furnish some mismated queens at 50 cents apiece. A. M. SAWDEY, Poolville, N. Y.

I have a few nice hybrids for 25c each, and a few rather small, untested and tested, for 40c. All are warranted to be good queens.
C. WECKESSER, Marshallville, O.

I have 10 good hybrid queens that I will sell for 25 cents apiece. O. E. HEACOCK, Volusia, Fla.

Prolific hybrid queens for sale, at 40c each.
WM. BARTH & BRO., Petersburg,
Mahoning Co., O.

I have several black queens at 15c; hybrids, 35c, to sell for neighbors—10 or 12 in all.
JNO. C. CAPEHART, St. Albans, W. Va.

UNTESTED CARNIOLANS.

I have about 50 Carniolan queens of last season's raising, fertilized by Italian drones, producing the gentlest bees and best honey-gatherers I have ever had, and a few of their daughters, untested, procured by natural swarming, which I will send by mail, and guarantee safe arrival, for 50 cts. each.
S. W. MORRISON, M. D., Oxford, Chester Co., Pa.

DO YOU EAT CANDY?

Send $1.25, and I will express 5 lbs. of Todd's Honey Candies, same as made a sensation at last Pennsylvania State Fair. Remember, every pound sold helps the honey-trade. Special rates for quantities for fairs. Dadant Foundation always in stock at market prices. Bees, Queens, Hives, Smokers. Vol. I of Frank Cheshire's new book mailed free, $2 50.
914db ARTHUR TODD, 1910 Germantown Ave., Philadelphia, Pa.

ITALIAN * QUEENS.

Very choice tested, $2.00 | Choice untested, $1.00
Circular free. WALT S. POUDER,
13tfdb Groesbeck, Hamilton Co., Ohio.

QUEENS.

I have them, bred from a best selected queen of Root's importation, 90 cts. each; 6 for $4.50. I can give all orders immediate attention, and ship by return mail. Send postal for dozen rates.
10tfdb **B. T. BLEASDALE,**
596 Woodland Ave., Cleveland, Ohio.

ITALIAN QUEENS. Untested, 85c.; six, $4.50. Tested, $1.50. Write for price list of bees, fdn., etc.
13-15db JNO. NEBEL & SON, High Hill, Mo.

QUEENS AT REDUCED PRICES.

As money is scarce, I will sell my warranted queens at $8.00 a dozen, or 2 dozen for $15.00.
13d J. T. WILSON, Nicholasville, Ky.

ITALIAN BEES FOR SALE.

7 strong colonies in Kidder hives; frames 10¾x11¾ inches, at only $5.00 per colony. Address
13-14d W. J. HILLMAN, Green River, Wind. Co., Vt.

By Return Mail.

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

SECOND QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

These prices are good only when you take a full roll. If you order less than a roll we charge 2c. per sq. ft. Sometimes the roll you order is gone before your order reaches us, in which case we send the next largest roll, unless it is a great deal larger.

SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED.

This wire cloth is second quality. It will answer nicely for covering doors and windows, to keep out flies; for covering bee-hives and cages for shipping bees; making sieves for sifting seeds, etc.

Inches Wide.	No. of Rolls.	Number of Square Feet contained in each Roll Respectively.
36	59	21 rolls of 217, 37 of 216, 2 of 215 s. f.
28	2	2 rolls of 233 s. f.
38	27	23 rolls of 316, 2 of 317, 1 each of 632, and 285 s. f.
48	1	1 roll of 400 s. f.

FIRST QUALITY WIRE CLOTH AT 1¾ CTS. PER SQUARE FT.

The following is first quality, and is worth 1¾ cts. per square foot. It can be used for any purpose for which wire cloth is ordinarily used; and even at 1¾ cts. per sq. ft. it is far below the prices usually charged at hardware and furnishing stores, as you will ascertain by making inquiry. We were able to secure this very low price by buying a quantity of over one thousand dollars' worth.

Inches Wide.	
24	39 rolls of 200 sq. ft. each.
26	55 rolls of 216 sq. ft. each; 1 each of 199, 195, 201, 200, 227, 204 sq. ft.
28	71 rolls of 233, 10 of 224, 6 of 222 sq. ft.; 1 each of 257 sq. ft.
30	25 rolls of 250 sq. ft.
32	13 of 266, 4 of 256, 1 of 275 sq. ft.
34	25 rolls of 283 sq. ft. each, 1 of 198 sq. ft.
36	15 rolls of 300 sq. ft. each; 1 of 288 square ft.
38	1 roll each of 300 and 316 sq. ft.
46	1 roll of 192 square feet.

A. I. ROOT, Medina, Ohio.

NORTHERN-GROWN QUEENS.

If you think them hardier, send me an order for queens, warranted pure Italians, bright colored. Any one buying five queens, I will send him one pair of standard W. L. chicks free. Price of queens, $1.25; price of chicks, $2.00 a pair.

C. A. DEARBORN,
14-16db Hudson, St. Croix Co., Wis.

ONE-DOLLAR QUEENS.

I will give you a printed guarantee of purity of every untested queen sent at $1 each before Sept. 15.
14 16db J. B. HAINS, Bedford, Cuyahoga Co , O.

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey.*—Owing to the writer's absence from business on account of sickness, we have not been able to furnish quotations of late in regard to the honey market. In future we shall be glad to quote regularly as usual. We quote: There is considerable old comb honey in market yet, for which there is but little demand at prices ranging from 8@10c for a fair grade of white-clover honey. Buckwheat unsalable. Our market is stocked with California extracted honey, which sells at 5@6c per lb. New Southern strained is coming to market quite fast, and is sold at from 50@55c per gallon.

Beeswax.—A good run of yellow, at from 22@24c per lb.
THURBER, WHYLAND & CO.,
July 3, 1886. Reade and Hudson Sts.,
New York, N. Y.

MILWAUKEE.—*Honey.*—The supply of honey is much better, both in quantity and quality. The new is very nice indeed. The demand is not large. We will quote white choice 1-lb. sections, 16@17; white choice large sections, 15@16; dark, nominal, 10@15; extracted, in tin, white choice, 7@9; extracted, in bbls. and kegs, 6@7. *Beeswax*, 24@25.
June 29, 1886. A. V. BISHOP,
142 W. Water St., Milwaukee, Wis.

DETROIT.—*Honey.*—New honey is coming in quite freely, and is bringing from 11@13c. The quality is generally better than for years. *Besswax* firm at 25.
July 12, 1886. M. H. HUNT,
Bell Branch, Mich.

FOR SALE.—About 400 lbs. of extracted honey.
EDWIN STUBB, Wakefield, Lancaster Co., Pa.

FOR SALE.—6000 lbs white-clover honey, at 6½c in bbls. of 555 lbs., or in 100-lb. kegs, at 7c. Satisfaction guaranteed. Honey thick and well ripened.
ROBT. QUINN, Shellsburg, Iowa.

WANTED.—To buy from 200 to 500 lbs. new white-clover honey in 1-lb. sections. References furnished. Address C. H. OSBORN, JR.,
Cor. 5th Ave. and Hunter St., Columbus, Ohio.

WANTED.—A few hundred lbs. of A No. 1 extracted honey, delivered here, at 7c per lb. Write stating quality and conditions, and I will give shipping directions. D. S. HALL, So. Cabot, Vt.

CIRCULARS RECEIVED.

The following have sent us their price lists:

J. W. H. Fisher, Franklin Mills, Pa., Albino and Italian queens and bees.

B. Walker & Co., Capac, Mich., 4-page circular of apiarian supplies. One-piece sections and reversible hives a specialty.

S. Valentine & Sons, Hagerstown, Md., 6-page supplement, the Success hive; also apiarian supplies.

CONVENTION NOTICES.

The Illinois Central Bee-keepers' Association will hold its next meeting at Mt. Sterling, Ill., on Tuesday and Wednesday, Oct. 19 and 20.
J. M. HAMBAUGH, Sec.

The St. Joseph Inter-State Bee-keepers' Association will hold its annual meeting on Wednesday eve of Exposition week, Sept. 1. Programme later.
E. T. ABBOTT, Sec.

COLONY in 10-frame hive, $5.00; tested queens, $1.50; untested queens, 75 cts.; 2-frame nucleus, $1.50; 3-frame nucleus, $2.00 (no queen). I have Italian bees; size of above frame, $9\frac{1}{8}$x$17\frac{5}{8}$.

Foundation-Mill For Sale.

One ten-inch Root comb-mill, second hand. The mill has, however, been completely fitted up, painted, and varnished, and is, to all appearances, both in looks and quality of work, equal to a new one. Price $15.00. The list price of a new mill of this kind is $20.00. **A. I. ROOT, Medina, O.**

CARNIOLAN QUEENS.

Having located an apiary of this new race of bees in an isolated place, surrounded by high mountains, where a honey-bee was never seen until we placed these there, we have two of the finest queens Mr. Benton could furnish to breed from, and can furnish queens of undoubted purity at the following prices:

June 1,	Queen,	$3 50;	½ dozen, - - - - $18 00
July 1,	"	3 00;	" " - - - - - 15 00
Aug. 1,	"	2 50;	" " - - - - - 12 00
Sept. 1,	"	2 25;	" " - - - - 10 50

ITALIAN ❊ QUEENS

of the best strains, bred in a separate apiary, 40 miles distant, warranted purely mated:

June 1,	Queen,	$1 00;	½ dozen, - - - - $5 00
July 1,	"	1 00;	" " - - - - - 5 00
Aug. 1,	"	1 00;	" " - - - - - 4 50

RAGWEED, MAYWEED, SMARTWEED, ET AL., VERSUS SWEET CLOVER.

IS SWEET CLOVER A BAD WEED?

MR. C. FAUST, of Harvard, Ill., desires that I should give in GLEANINGS the facts in regard to the character of melilot, or sweet clover. He says in his region it has been planted largely along the roadsides, but it is being cut by the farmers, as they refuse to let it grow and seed, for fear it will become a serious pest in their meadows and cultivated fields. Mr. F. adds, that it is this beautiful plant with its rich product of superior honey, or else ragweed and mayweed, which he feels sure are important factors in the production of "hay fever." I have no knowledge in reference to the part ragweed and mayweed play in the production of hay fever; but I have raised sweet clover now every year at the college for several years, and I feel certain of the following points:

1. Sweet clover is a very excellent honey-plant; 2. It is very beautiful, both from its rich fine foliage and graceful sweet-scented blossoms. Surely ragweed, mayweed, smartweed, etc., bear no comparison to it as an adornment to the highway; 3. It is not bad to spread at this place. We rarely find it starting at any considerable distance from our beds; and when it does start in meadow or pasture it rarely holds on, being choked out by our cultivated grasses; 4. When once started it is no difficult matter at all to get rid of it. As is well known, this clover is a biennial, and grows from seed flowering the second year. Thus by cutting while in bloom, or before the seeds mature, we shall quickly extirpate it. It can not remain longer than two years after such cutting, as it must come from seed every other year.

So I am free to urge the farmers of Illinois and other States to foster rather than destroy this plant. They will thus adorn the roadsides, and will also aid to foster and develop an important industry.

At this writing our beds of sweet clover—melilot (*melilotus alba*) are in full bloom, and it is hard to say which is more attractive to the bees—this or the basswoods, which are also in full bloom.

Agricultural College, Mich. A. J. COOK.

Friend Cook, I agree with you exactly. Sweet clover has been on our grounds several years. In fact, we had half an acre at one time, and the seed was hardly ever gathered, and hence it came up so thickly it could not grow. For about one year it was a little troublesome. Since then it has entirely disappeared. None of it is found on our grounds at all, unless it is an occasional shoot that comes up among the strawberries and in such places. It is true, they are a little hard to pull; but after a soaking rain they will come up as well as docks, or other kinds of clover. Now, while it is true that it doesn't hold its own in cultivated fields, it is also true that sweet clover will grow in any kind of hard yellow clay right by the roadsides, or on barren hills. Dr. C. C. Miller, as you will remember, suggested as a reason for this (see page 441), that it seems to endure any kind of treatment or hard usage. On that account it gets a hold along the roadsides when it is not found elsewhere. Bee-keepers have been accused of sowing the seeds along the roadsides about Medina; but I don't think any bee-keeper would take the pains to do so. It simply got a start along the roadsides, and has been following along year after year. I do not know that I ever saw a patch of it anywhere in cultivated fields, and I never knew it to do any hurt.

CANADA THISTLES.

Now, while I am on this subject I want to say that we have recently found a patch of real genuine Canada thistles on our grounds. They were first found close to the fence on the opposite side of the road from our county fair-ground; and the supposition is, that somebody unpacked some goods, or fed his horses some hay up against our fence, and this hay contained the thistle-seed. They are scattered for a rod along the road under the fence, and had got, perhaps, ten or twelve feet over into our field. The minute I found them I dug up every plant visible; but in ten days after, although we have not had a drop of rain, they are coming up as thick as spatter. Sometimes a new strong plant will be found fully six feet further out in the field than any other had been before. It looks as if it might make a power of trouble; but I rather like the fun of trying my hand on such a foe. Will some one who has had experience tell me how long it will live if I chop up the plants every ten days all summer long? The roots seem to run in the ground like moles; but the question is, How long will the roots live if they don't have a chance to make leaves?

MARKETING COMB HONEY.

HEDDON'S METHOD.

IN your foot-notes at the close of my article, page 542, on "Getting Bees out of Sections," you request me to follow up the sections to market, and I will gladly comply with that request; for my experience in the matter, together with conversation with commission men, has convinced me that it is a serious mistake to send honey to market in the same cases or crates it was stored in, on the hives.

On page 854 of GLEANINGS for 1885 is illustrated and described the shipping-crate of my own invention and choice. In this crate, friends Hutchinson and Taylor market their fine comb honey, and in it they have carried off the liberal premiums offered for best display of comb honey, by the Michigan State Agricultural Society, ever since it offered them. I might further state, that the honey was in 4¼ × 7-to-the-foot, 4-piece, dovetailed, white-poplar sections, and stored in my non-separator case. Now, do you think any person could have successfully competed for these premiums by showing ever so nice comb honey in the same crates the bees built it?

Our honey-house is a large airy room, made and kept as neat and clean as a dwelling-house. From the screen-house, mentioned on page 542, 1886, we carry the storing-cases to the honey-house, piling them up crosswise, that the air may freely circulate through them. As soon as we need the cases, and spare time admits, we invert them on our honey-table, push out the sections in a minute, and, holding them over a box, with the point of a medium-sized blade of a pocket-knife we scrape all the glue from their edges and place them in the shipping-crate above referred to. The glue being now quite cool, readily lets go the wood. With a little practice the apiarist will hold the blade between thumb and finger in such a manner as to rarely, if ever, mar a capping, and will do the work very quickly.

Once, in conversation with R. A. Burnett, of Chicago, who handles large quantities of comb honey, after telling him how much time it required to clean and crate the sections, he said that the difference in price and attractiveness would pay us enormous wages for the labor performed; one or two dollars per hour would be a low estimate, I think.

We now pile our crates up in the honey-house, keeping them there any length of time we desire, never having any trouble from worms, fermentation, nor granulation, if not kept all winter without fire. These little crates cost less, and look much more attractive, than storing-cases. As stated in my article on page 854, 1885, these small crates ship safer, and sell more readily. They also cost less than storing-cases. A dealer who has once handled honey in these crates will be loath to receive it in cases as it comes from the bees. For convenience, let us agree to call storing-cases *cases*, and shipping-crates, *crates*.

REVERSING.

I have been interested in reading Ernest's apiary reports on page 550 and 551. Yes, sir; he is right; reversing has come to stay. If he will experiment on a comprehensive scale with my all-wood reversing device he will like it, I think, much better than the Simplicity, shown in the cut. It is not attachable to old frames, I admit; but I feel sure it is much the best when constructing new ones. We have had considerable practice in reversing the whole hive at once; so has Mr. J. M. Shuck, of Desmoines, Ia., and I believe that neither of us have as yet observed any detrimental effect whatever from such reversal.

Referring to page 537, 1886, I would say to Mr. Ritter that we can not practice his modification of modern transferring, for our bees usually have brood in spring, before they fly; but we have several times performed it in autumn, after brooding had ceased, as mentioned by the editor in his foot-notes.

Referring to page 536, on "Preventing Increase," it is quite easy to see why Mr. Robbins failed of success, while Mr. Hutchinson, myself, and others, have never met with failure. JAMES HEDDON.

Dowagiac, Mich., July 5, 1886.

Thank you, friend H. You have given us just exactly what I wanted you to give; and even if some of the matter has been given us before, it comes now right connectedly, and in practical shape, and in just the season when we are ready to use it. I know something about the difference it makes in having the sections clean. Our boys on the wagon told us a short time ago that there were calls for honey, made this year. I remarked, that it would not make much difference whether it were new or old, but we would try to give them some just from the hives. The first lot we got hold of was nice, white, clear honey, but it was darkened by being left on the hive too long, and some of it was stored in sections that had been on the hives the year before. It did not sell a bit better than the old honey. Finally one of our progressive young men from a neighboring town brought in some new honey in new white cases; in fact, the stuff for the cases hadn't been a week out of our saw-room, probably. The sections were so clean and white that one might suppose it hadn't been a week since they left the buzz-saw. He wanted 15 cts. a pound for it. I paid it, although I gave only 12 cts. for the former lot. Well, this clean nice bright comb honey is selling at a good rate for 18 cts. per lb. We just put the case right on the wagon, and the appearance of the honey sells it right along. I might add, there is not a bit of propolis visible anywhere. While I think of it, friend H., perhaps I should also add that neighbor Chase, the young man who brought us the honey, is using surplus-arrangements like or similar to those you used a year ago.

BORAGE AS A HONEY-PLANT.

A GOOD REPORT FROM IT.

I SHOULD like to say a few words in praise of what I think to be one of our best honey-plants; i. e., borage. I got enough seed from you last year to plant about ½ acre, but sowed it rather late. However, the bees worked on it until late in November. I did not save the seed, but let it seed itself. It commenced to bloom about the 1st of May, and the bees (mostly blacks and hybrids) have been just *swarming* on it ever since, even during poplar and white clover. The remarkable part about borage is, the bees work on it after a heavy shower. The head of the flower, as you know, hangs down, and the rain does not wash out the honey. I wish to put in a large crop of it next season. We have had a great deal of rain here of late, and the bees are getting a very clear, sweet honey, very much like sugar and water. I send you a small sample. Can you tell me what it is? I have also noticed some of my honey capped over with yellow wax, as described by J. W. Porter, in June GLEANINGS, p. 480. Italians will utilize wax when they have access to it; and as I had left some fdn. in an old Palace hive, and saw them at work on it, I accounted for it in that way. Am I right?

R. R. CUYLER.

Rapid Ann, Va., June 27, 1886.

I am glad to get so good a report from our old friend borage. We have raised it a good many years, but we have such a very large number of bees working on a small plat of ground that it is difficult to tell how much honey the plant furnishes, or any thing about it. The sample of honey you send is very nice. I will explain to our readers, that it is just about right to drink. The flavor is a little different from any thing I have ever tasted in the way of honey, but I should call it fully equal to clover, so far as I can judge from any thing so much diluted. It is probably borage honey, just as it is gathered. During a very wet season I once had some clover and basswood honey almost as thin as this. It would run out of the combs when they were turned up in taking them out of the hives. If removed by the extractor in this condition it will quickly sour; but if left until the bees seal it up after their own fashion, it will be nice thick honey. I should be glad of more reports from borage. It is very easily raised, and, as you say, may be put in quite late. It self-sows, so that, if the seed is not gathered, it may prove to be a troublesome weed; but not more so, however, than buckwheat or other similar plants.

EMPTY BROOD-NESTS.

NEW SWARMS—EXTRACTED HONEY.

YES, friend Root, I have tried working new swarms for extracted honey, and I see no difference in regard to whether the *brood-chamber* shall be furnished with combs or fdn., or the bees allowed to build their own *brood*-combs. You say: "Of course, this condition of affairs refers to comb honey. When one is working for extracted honey, by all means give them empty combs." Yes, I would give them empty combs, but *not in the brood-nest*. I would furnish the frames in the brood-chamber with starters of fdn., put on a queen-excluding honey-board, then a super filled with empty combs; or, if I had no combs, I would fill the frames in the super with fdn. The principle of allowing the bees to build the combs in the brood-chamber, and furnishing comb or fdn. in the supers, is a broad one, and it really makes no difference whether the honey in the super is to be extracted, or whether the combs of honey are removed in the shape of pound sections. Just stop and think a moment, friend R., and see if you can't "catch on."

W. Z. HUTCHINSON.

Rogersville, Genesee Co., Mich., June, 1886.

I confess, friend H., I don't "catch on" exactly; but I begin to suspect that bees will store more honey if they are permitted to indulge their passion for comb-building to a certain extent than if they are given so many combs they have no room to build new combs at all. D. A. Jones says, "We are fully convinced that full frames where extracted honey is taken is a decided advantage."

HOW TO RAISE CELERY.

FRIEND A. T. COOK GIVES US A PLAN BY WHICH EVERY FAMILY WHO OWNS A PATCH OF POTATOES MAY RAISE CELERY.

THE potatoes, when plowed and well hilled up, will leave just the trench required for the celery-plants. Stir some fine fertilizer in the soil and set out the plants, six inches apart in the rows, pressing the soil firmly about the plants. Set every other row with celery, and this will leave abundance of room for earthing it up after the potatoes are removed.

After setting the plants, water well; and then with a rake draw the potato-tops over the rows of celery to shade them from the hot sun. After a couple of weeks turn the potato-tops back; and by the time the celery needs earthing up, the potatoes will be ready to dig; after which the celery may be plowed and hilled up in the usual manner. I raise celery in this way with half the time and trouble of any other plan. I am unable to see that either crop interferes at all with the other—indeed, the potatoes, as a shade for the young plants, are a great advantage.

FRIEND COOK'S METHOD OF REMOVING POTATO-BUGS.

It may not be out of place to tell my way of catching potato-bugs. I never use poison. I put a large bale, made of a barrel-hoop, on a common tin pan and then fasten a pasteboard, 8 or 10 inches wide, on one side of the pan, reaching half way around. This prevents the bugs from flying over when I brush them in. I use a brush made of broom corn, which does not injure the vines; and if bugs are plentiful I go over the vines every other day. A. T. COOK.

Clinton Hollow, N. Y.

"BEES AND BEE-KEEPING."

A REVIEW OF THE SAME BY PROF. COOK.

IT is only from lack of time that I have delayed reviewing this excellent work, the first half of which has now been in the hands of bee-keepers for some weeks. This part of the work is wholly scientific, and is very thorough and complete. I can hardly describe the interest and pleasure I have derived from its careful study. This is not lessened by the fact that its criticisms of my own work seem rather harsh. When I am wrong I am only too glad to be corrected; and if, in my intensely busy life, I have at times been too hasty or less careful than I ought to be, it may be well that I should receive even a sharp reminder. Of the six or seven points criticised, two were corrected before I saw this work; and if the other criticisms are found, upon examination, to be well grounded, as will very likely prove true, I shall certainly profit by them. As Mr. C. says, I drew largely from Hyatt's monagraph. He has done the same, yet he does not even hint that I differed totally from Hyatt in the structure of the ligula and the process of taking nectar, or that I was first to give the description which he substantially follows. When I first read Mr. Cheshire's article on the cause of foul brood, and noted how he spoke of the German scientists who had discovered the cause of the malady, I wondered that so good a scientist could mar his work by such unkind references, especially as his own work is largely compilation, though he has given us much which is new. This latter, if correct, as it doubtless is, in the main, gives us great reason to thank him.

In this review I shall speak only of some of the most interesting points of the work, suggesting that, while it is rather technical in places, for the unscientific reader, no live bee-keeper can read and study it without great benefit.

Mr. Cheshire is a skillful microscopist, and it is in this field that he has done the principal, original work. It is generally known by scientists that larval bees, no less than the larvæ of other insects, shed their skins. The author shows just how and where these discarded garments are tucked away. I have found that these shreds of the rejected skins of bumble-bee larvæ are managed in similar fashion. It is stated that the cocoons extend but a short distance from the outer end of the cells, and that Huber was wrong in stating that those of queens were much less extensive than those of the other larvæ.

No part of the work is more interesting than that describing the glands of the mature bees. He calls attention to the three pairs of glands, two in the head and one in the thorax, which were pointed out by Siebold; also the flask-shaped gland at the base of the mandible, which is beautifully illustrated by Wolff in his admirable monagraph. Mr. Cheshire argues, and with no small show of reason, that one pair of these glands of the head secretes the most of the food of the larval workers, nearly all of that of the larval queens, and the most—all of the nitrogenous food of the queen. The fact that this gland is absent in the queen and drones surely gives strong support to the view, as does the fact that the gland seems more active in young than in old bees. It is argued, that the other glands are digestive in function, and probably serve to convert the cane sugar of nectar into the reduced sugar of honey. Here Mr. Cheshire makes a strange error, in the statement that our saliva is wholly a digestive liquid; that it changes starch into sugar. It is well established, that our saliva is almost wholly mechanical in its function, and that the pancreatic juice digests the starch; though I think we can hardly doubt Mr. Cheshire's proposition, that this secretion of bees is digestive in its action.

In commenting upon the fact that the queen is probably fed, when she is actively engaged in laying, upon the rich secretion which affects the rapid development of larval bees, it is estimated that the queen lays eggs to double her own weight each day. Surely, she needs good food, and to have it well prepared. Fancy a hen laying from twelve to twenty pounds of eggs a day! Is it possible that we may secure such fowls by taking hint from the bees, and preparing a rich diet already suited for assimilation? If so, we must remember that nature has been very slow in developing her marvels, and we must copy her and not hurry.

The description of the alimentary canal is very full, and as full of interest. The explanation of the stomach-mouth of Burmeister, and its valvular and separating functions, will be read with much interest. This method of separating pollen from honey shows how skillful nature is in her operations, and explains why honey has so much less pollen in it than does the nectar from which it is derived. It is shown that the intestine of bees serves as a gizzard; and the suggestion is made that the intestinal teeth serve the purpose to break or cut the still undigested pollen grains.

The part of the work treating of the mouth parts will be read with no small interest by the bee-keeper who loves science. Mr. Cheshire thinks the peculiar tongue-structure, which, if I mistake not, I was the first to correctly describe and illustrate (see fig. 22, Manual) serves the purpose of cleaning out pollen grains which may find lodgment in the central slitted rod, or plicated membrane, uniting edge of rod and edge of outer case. Thus the bee has no need of a toothpick, as the evolution of the tongue itself serves to clean it.

No part of this work will be studied more profitably than the description of the antennæ. The histology of these organs is well portrayed, both by words and figures. Mr. C. contends, with much show of reason, that these complicated and very useful organs serve not alone for touch, but also for hearing and smelling.

The legs are fully described and illustrated, and their complex and wonderful structure explained, as also the function of each part. It is suggested that the jaw-like arrangement between the basal tarsus and tibia serves as pincers to grasp and carry the wax scales from wax-basket to mouth. The claws and pulvilli are also described, and their purpose to hold on is correctly stated; but that this is new is certainly wide of the mark.

The structure of the sting, and the way it is used, is well given, and is substantially the same as given by Hyatt.

I have not space here to more than refer to the wonderful description of the spermatheca, and the manner in which eggs are impregnated, or passed unimpregnated, at the will of the queen.

This, with other parts of the work, show the author to be an expert with the microscope, which fact, combined with a skillful pencil, makes the treatise of great value.

The last part of the work, showing how useful bees are to plants, is most opportune just at this time. The author has selected wisely from Darwin's great work on this subject, and has given graphic examples of the value of bees to fruit-growers. The work is beautifully executed, and is certainly a great credit to its author, and a most valuable acquisition to bee-literature. It is to be regretted that its price is so great—$5.00 for the entire work, $2.50 for each volume—as this will keep it from the libraries of a great many who would otherwise secure it. Yet it is hard to see how it could cost less. A. J. COOK.

Agricultural College, Mich., July, 1886.

Thanks, friend Cook, for your kind and deserved notice of this valuable work. I am pleased to see, also, how well you "stand fire," if I may be allowed the expression. So long as we are all human, and liable to err, especially when we try to search out the depths of natural history, why should we not have a very wide charity for each other? Of course, a good deal of the above is beyond my depth; but may I be excused for venturing to criticise both you and friend Cheshire on one point? You know it has often been said that a queen will lay eggs enough to equal her own weight in 24 hours; but it seems to me that this is surely a mistake, and I want to inquire if you have at the Agricultural College a pair of scales equal to the task of weighing a queen's egg, or, if you choose, 100 or 200 eggs. Suppose we grant that a queen may lay 3000 eggs in a day, will these eggs weigh any thing near as much as the queen herself, say at a time when she is not laying eggs? A great part of my life has been spent with small scales—those for weighing gold and silver. From the experience I have had I can not think that the above statement is correct. One of the poultry-journals a short time ago suggested that it was next to impossible for a common fowl to eat and digest food enough every day to produce an egg; that the way she managed it was to accumulate flesh before she commenced laying; and when this accumulation had disappeared she was obliged to take another rest. Well, there is a "biddy" down at our poultry-house that has laid an egg every day since last February; that is, if she has missed a day I have not noticed it. She was quite a small fowl when she commenced to lay, and I should say she had increased in size fully a third while she has been laying. So this upsets the point made in the poultry-journal. Perhaps I should add, however, that the eggs laid are remarkably small—so small they would hardly answer for market. The hen is a cross between Plymouth Rock and Leghorn. She was hatched so late in the fall that she was probably stunted in growth during winter. She takes enough food to furnish material for an egg every day, and something more, which makes me look at her in amazement quite often. Now, then, can a queen, even with thousands of attendants using their digestive apparatus to help her along in her work of egg-producing (by giving food in the most concentrated and fully digested shape possible), produce eggs enough *in one day* to weigh as much as she does? It may be true, but I should like to see it proven. When it is I will take off my hat and make my best bow to a queen-bee, in token of the great wonders the inmates of a bee-hive are capable of performing.

GETTING BEES OUT OF SECTIONS.

THE WAY FRIEND DOOLITTLE MANAGES IT.

I NOTICED George A. Wright's question on page 393, regarding getting bees out of sections, and it would have been answered sooner, only for pressure of business. As I have very little time at my command I will tell, as briefly as possible, just how I manage; and as July is our great honey month here at the North, it will be in good time for all those whose surplus is obtained from basswood or fall flowers. All have noticed that the bees have passageways, or holes, in each of the four corners of nearly every section—so much so that these holes come as near being a matter of fact as any one thing connected with bee culture. Now, it will be seen that, in our plans of later years, these sections are so placed upon the hive that these holes in the corners make one straight hole right through from one side of our case, or clamp, of sections to the other, nearly or quite as straight as if bored with a ⅝ auger. This, I think, I have made plain to all. Then all know that, if smoke is suddenly poured into a bee-hive without any jar or disturbing beforehand, the very first thing the bees will do is to run as far from the smoke as possible, inside the limits of the hive, without stopping for any thing. As soon as such limits are reached they will take to their honey, for they will not leave the hive without taking a load of honey with them for a new start in life. Taking advantage of these two facts I carefully lift the cover to the hive, and just as carefully remove one of the little side boards from my section case, or clamp, of wide frames, blowing a little smoke upon the bees on the face side of the sections, and, as quickly as possible, hold the nozzle of the smoker to the first of those holes at the upper corner of the sections, beginning on either the right or left hand side as it comes handiest. I now give two puffs of smoke into that hole, working the smoker for all it is worth, so as to send a stream of smoke as deep into the sections as possible. Then the nozzle is placed at the next hole, and the next, and the next, in quick succession, till two puffs of smoke have been driven as far as possible into each hole. I now quickly take off the little board on the opposite side of the clamp, and as thoroughly drive the smoke to the heart of the section-case from the other side. Now I wait a moment, giving the bees the necessary time to flee from the smoke, when the sections are suddenly taken from the hive with scarcely a bee upon them, if I have done the work as it should be done. Immediately after, a reaction will take place, especially where a small brood-chamber is used, and the bees come boiling up over the frames, and, if the sections are not off, up into the sections, when all the smoke we can use will not drive them so but that they will fill themselves. In this way I get off my sections free from bees, and never, as a rule, get holes gnawed through the capping of the cells as I used to before I learned how to do it. In times of scarcity of honey in the fields, the bees will sometimes stick to the lower portion of unsealed sections; but as these are not marketable, no especial harm is done. However, it is a rare case that all do not go out. The only secret there is to it is to know the right time to take off the sections; just that moment when all the bees are out, and before any return. A little practice will secure the reader that secret.

Borodino, N. Y., June, 1886. G. M. DOOLITTLE.

We have tried the same thing, friend D., but we did not all succeed as well as you state, on account of this same reaction; that is, after the bees had all gone out of the sections with a roar they came trooping back again before we got round to taking off the case of sections. With the suggestion you give us, however, I think now I can manage it; but we want our honey-crates so they will lift right up without any prying or snapping. Heddon's sink honey-board will probably help in this direction.

A BEE-SMOKER THAT USES NO FIRE.

OUR ENGLISH FRIENDS TAKING THE LEAD.

AMONG the advertisements in the *British Bee Journal* for June 24th we see advertised Webster's fumigator. The advertisement states that it entirely supersedes the smoker—no going out, as no fire is used; no tainting the honey. The agent used is carbolic acid, oil of tar, and water, properly mixed. The proprietor advertises a bottle of the mixture—enough to last two seasons—for 6 pence. He also says the instrument can be adjusted by any novice to any ordinary smoker-bellows. We judge from the advertisement that the agent is placed in a sponge. By means of a fumigator, the air is made to pass twice over the sponge, so as to be thoroughly impregnated. An arrangement is also used to prevent evaporation of the liquid when not in use. Our friends may remember that this subject has been discussed and experimented on before, although I believe none of us have thought of using carbolic acid. We ordered a fumigator and extra bottles of the agent, and will report in due time. We do not notice any thing in the reading-columns in regard to the invention, but it seems to me it promises to make a great revolution in the smoker-business. I, for one, protest against any patents, especially among our American friends. Let each one experiment freely as much as he chooses. Among the testimonials we do not find the names of any we know, except Frank Cheshire, and from him only this brief note:

> I find, by experiment, that the most vicious of Eastern bees are utterly beaten at once.

WHY DID THE QUEEN MENTIONED ON P. 485 STOP LAYING?

A CORRECTION.

ON page 485 David Strang asks, "Why did the queen suddenly stop laying?" I do not think she had ever begun. He says, "I released her from a cell partly destroyed by a rival, and introduced her to an artificial colony, formed about 12 hours before, of frames and bees from three or four colonies. She was accepted, and a week later had nearly four frames full of eggs and young brood," etc. Then four days later, not an egg or an unsealed larva could be found in the hive. In the first place, a queen will never, as far as I have observed, have 4 frames filled with either eggs or larvæ in seven days from the time she is hatched. I have raised a great many queens, and I never had one mated in less than five days after hatching, and it is generally seven or eight; then it is from three to five days after they mate before they begin to lay.

The eggs and larvæ that he found in the hive were probably in the combs when he put them in the hive. The reason that the eggs had not hatched into larvæ was because, it being a made-up colony, the old bees had all gone back, leaving only the young bees, and there was not sufficient heat to hatch the eggs that were not under the cluster. The reason he did not find them later was, that they had sealed over what brood had hatched, and eaten up or carried out the eggs that would not hatch.

THE SCARCITY OF CLOVER IN BOURBON COUNTY, KANSAS.

Bees are doing better here this season than I ever knew them to do in this part of Kansas. There is no white clover here. I do not think all the white clover in this county would make a good stand on a half-acre; but I have three or four acres of alsike sown this spring, and it looks well; but there seems to be a good natural supply of honey. From 18 stands in the spring I have extracted 640 lbs., and increased by natural swarming and dividing to 30, and the best part of the honey season is to come yet. There are a great many bees kept in this part of the State, but nearly all in box hives.

A FEW OLD FOGIES STILL LEFT.

I went to see a man last week who has 45 stands in boxes. He says he doesn't want any new-fangled patent gums. I told him there was no patent on them, but that didn't make any difference. He wouldn't give his old box gums for all the patent hives that ever were made; and when he wants honey he takes his sulphur-pot and kills the bees and destroys the brood and combs; but he is wise in his own conceit, and I could not tell him any thing. He was an old man, and had kept bees for over fifty years, and knew all about them.

JOSEPH C. BALCH.

Bronson, Bourbon Co., Kansas, June 26, 1886.

Friend B., I think you are right, and I beg pardon for having omitted to note that friend Strang, in his statement, said it was only a week after the queen was hatched that she had her frames full of eggs and young brood. I have frequently noticed that the eggs would remain in the combs several days, where, for some reason or other, bees did not nurse them nor care for them.

DO QUEENS WITH CLIPPED WINGS FLY?

HOW MUCH OF THE WING SHOULD BE CLIPPED?

I HAVE been reading GLEANINGS since April 1st, and some sample copies before that, but I am not familiar with what has and what has not been discussed in the past years; therefore if I tread over ground which has been trodden before, you will please excuse me.

Some time before swarming time, my brother and I went over our bees and clipped the wings of all the queens which had not been clipped before that, so we thought we need not be afraid of any swarms getting away. My brother George and I are partners in the bee-business, while my brother John has a few colonies independent of ours. A few days ago we were all three in the apiary, cutting the queen-cells out from a colony which had cast a swarm, so there would be no after-swarms. Suddenly John exclaimed, "There they go!" I looked around and saw a swarm issuing from a colony which had a clipped queen. I went to the hive, took off the cover, and picked up a queen-cage which I had placed on the enameled cloth some time before, and commenced looking for the queen, in front of the hive. We all three looked for awhile; and when we could not see her we proceeded to look inside of the hive. But we loooked in vain. By this time the bees had settled on a peach-tree some fifty or sixty feet away, and seemed very well contented.

"Well," said I to my brothers, "the way those bees sit there, they must have a queen with them; so I think we had better cut the limb and carry them to the hive, instead of putting them in a new hive on the old stand," as we had been practicing. I was somewhat puzzled at their capers, as I knew the queen's wings were clipped, and I also knew they could not have raised a young one, as I had been examining them quite often. We thought the queen might have got lost in the grass, so, after putting three frames of brood in the hive, one containing a sealed queen-cell from our choice queen, and filling the rest of the hive with empty frames, and closing it, we shook the bees in front of the hive, when they marched in very much as if they had a queen, and in a short time they were at work.

When looking in the hive the next day we found the queen-cell torn down. "Well," said I, "queens with clipped wings can surely fly." We did not see her then; but a few days later we found eggs, and after looking for her awhile we saw the old lady, evidently very well satisfied with her new home. Her wings were clipped, but not short enough. Now this, I suppose, is known to all veterans, and therefore may not be interesting for them to read; but there may be more young apiarists, like myself, who would suppose that a small portion of the wings clipped off is sufficient. To those, I would say, if you don't want your queens to fly, clip off nearly or quite half. Had we waited for the bees to return, thinking that the queen was lost in the grass, I think we should have been badly disappointed about the time the scouts returned. If the bees had no queen, would they have remained in the hive with the brood and queen-cell? S. E. MILLER.

Bluffton, Montgomery Co., Mo., June 18, 1886.

I think, friend M., if you will clip *one* wing it will do more to prevent the queen from flying than if you clip both; but instead of cutting the wing square off, run the scissors so as to take the thin gauzy portion, and leave the hard rib. It seems to hurt the queen more to cut this hard rib than to cut the web part; and this thin gauzy web is the part that does the flying. Of course, she can flop her drum-sticks to her heart's content; but so long as it does not help her to get up in the air, we have no objections.—Bees will remain contentedly without a queen, providing they have unsealed larvæ; otherwise they will generally desert.

BEE BOTANY,

OR, HONEY - PLANTS TO BE NAMED.

LIPPIA LYCIOIDES.

BY this mail I send you specimens, for naming, of a shrub which is probably the most valuable bee-plant in this portion of the State; height, 6 to 10 feet; delicate white flowers in spikes; highly aromatic; blooms from April till July, if seasonable, and after each heavy rain until the hard frosts in December. In fact, under favorable circumstances it is a perpetual bloomer. It is quite plentiful in this locality, and I am told that in some places it predominates. The honey is very excellent and abundant; but as it comes at the same time of mesquite, mint, and other flowers, it is difficult to keep the honey separate.

San Antonio, Tex. T. F. MCCAMANT.

Prof. Devol replies as follows:

The plant is *Lippia lycioides*, Gray, a member of the Verbena family. It is not described in the text-books of botany, but may be found in Gray's Synoptical Flora of N. America, Vol. 2, p. 338.

Columbus, O., June 7, 1886. W. S. DEVOL.

ANDROMEDA.

I send a few specimens of what is here called sugar plant, full of honey, but too deep for common bees to reach. Can Italians use it? It is plentiful hereabouts. W. V. SPENCER.

Prof. Devol says of it:

The plant from W. V. Spencer appears to be *Andromeda nitida*, Barto. I know no common name for it. It is a beautiful shrub, common in the low pine barrens of the Southern States. Some of the species of *Andromeda* are poisonous to sheep when eaten; but whether this one is, I can not say.

W. S. DEVOL.

CHINQUAPIN.

I send you a sample of what we call chinquapin. It is a great honey-plant. Please let us know its name. C. C. KIRKMAN.

Coxville, Pitt Co., N. C., May 29, 1885.

Prof. Devol says:

The inclosed plant is chinquapin (*Castanea pumila*, Michx.). W. S. DEVOL.

SWEET CICELY.

Seeing in GLEANINGS that you give the name of herbs and plants, I send one to name. I send you some of the stalk, leaves, and roots. W. W. GIGER.

Heltonville, Lawrence Co., Ind., June 9, 1886.

Prof. Cook's reply:

This is sweet cicely (*Osmorrhiza longistylis*). The name, from the Greek, means "scented root." The root not only smells sweet, but tastes not unpleasant. It belongs to the Umbellifera, or Parsley family. While the plants of this family secrete nectar, I do not think they possess any special excellence as honey-plants. This sweet cicely is common, north.

Agricultural College, Mich. A. J. COOK.

THE WORST BEES I EVER SAW.

ARE THEY CYPRIANS?

TO-DAY I had business inside a certain hive of bees that sits over there under that old mulberry, you know; and as I was lifting off the cover, not another provocation, mind you, said bees came in such "a rolling out, tumbling out, any way to get out," style from the entrance, that I was for a time dumbfounded. In a very short time I considered it not only my bounden duty, but to my best interests, to remove hastily from the situation; nor did I stand upon the order of my going. They covered me from head to foot, stinging my clothing all the while, nor could I get them removed till I had passed through four rooms; and through these rooms they sounded like bees swarming. On account of a good veil I received only three stings, and those upon my arms. I verily believe I should have been stung to death had I not worn a veil. I have as gentle bees as anybody else; but I wear a veil in handling queen-rearing colonies and in some other work.

Now, the above queen I know not where I got her; but I never suspected having such vindictive bees in my yard till this attack—a new queen whose second batch of progeny has just begun to work. In many ways they are the most remarkable bees I ever saw. The queen keeps *ten frames full* of brood, and I mean ten frames filled clear out—a most beautiful bee, large, and they work in and out with a rush, when my best pure Italians and Carniolans are plodding along, waiting for "something to turn up."

Now, I have "removed" this queen, and am introducing another, as I want no such bees. Who wants her for 35 cents? Bees are two and three banded. Don't say they are *hybrids*, for I have *them*, and never saw any to half equal these. Oh, yes! my wife says, "Don't forget to tell GLEANINGS about those bees stinging the chickens." Three or four little chicks are wabbling around from being stung by them. JOHN C. CAPEHART.

St. Albans, W. Va., June 26, 1886.

HOW FALSE REPORTS OF HONEY AND OTHER THINGS GAIN CREDENCE.

THE SUPERSTITION OF THE CHINESE.

DEAR FRIEND ROOT:—Reading in GLEANINGS recently the remark in regard to the alleged manufacture of spurious honey, that, "in view of the wonderful achievements of science it is no wonder that men believe that the nicest comb honey can be imitated," awakens a sympathetic feeling in my mind. The Chinese, when once they begin to get acquainted with our Western inventions, soon get clear beyond their depth, and don't know what to believe and what not to believe. I once saw a blind woman who had come two days' journey, where traveling was very expensive, to have the foreign doctor insert a pair of dog's eyes in her head. She heard that he could; and why not as well believe that as to believe that he could send a message through a hundred miles of iron wire?

There is one thing which has given us a good deal of annoyance at Shau-wu, our interior station. Not being ready to credit us with the benevolence which we profess, the Chinese must invent some theory to account for our readiness to come so far and spend so much money. Now, this old nation of China has passed through many revolutions and commotions, and so, from time to time, rich men have buried their treasures in the earth, and many of these have never been recovered. The theory commonly held among the people at Shau-wu is, that we have come to search for treasure. Somehow the story has been started that we can see three or four feet into the ground; and as we go about preaching and bookselling they claim that we go about peering into the ground for treasure. Once I was sitting on a ferry-boat watching the little fishes sport in the water while I waited for the boat to cross the river. A man eyed me curiously for a while and then asked of my Chinese helper, "What, can he see into the water? I have heard it said that foreigners can not see into water, but can see into the ground, just as we can not see into the ground but can see into the water." You see, they have the idea that we are opposite to them in most things, and they don't know how far to carry it. So far as concerns any superior skill we may possess, the unwillingness of human nature to acknowledge inferiority acts as a check on exaggerated notions of our powers; but when it comes to those things wherein we differ from them, they rather like to exaggerate, and make themselves believe that we depart in strange and unnatural ways from the true type of humanity, of which they, of course, are the grand embodiment.

One thing in regard to which they are strenuous, and think themselves better than other races, is the proper seclusion and subordination of women. The Christian treatment of women is something which they fail to comprehend. They seem to regard it as a part of the curious tendency to invert every thing which they think characterizes the "outside" nations, and so men must be subordinate to women with us.

To-day I sat chatting with a crowd in a shop opposite one of our chapels, where the gospel has been preached regularly for many years. One of them said to me, "With you the women control every thing, do they not?" I replied, "No: with us, husband and wife consult together on all their affairs. The husband is the stronger, and if he choose to impose on his wife she would have to bear it. But we consider it disgraceful for the strong to impose on the weak; and a man who ill treats his wife would be ashamed to show his face."

Another man inquired, "With you the women 'seek' the men and 'call' them to be their husbands, do they not?" I answered, "No, indeed. With us it would be thought disgraceful for a woman to seek a man in marriage."

Seldom do I converse with a crowd of Chinese but that I have to answer these questions; and all this in or near the city of Foochow, where missionaries have lived and toiled for forty years.

At our Shau-wu station we were troubled for a time with a worse slander. In the beginning of our work there it was reported that we bought children, and even sometimes women, and killed them, and made them up into medicine. The Chinese think that strength and vigor can be imparted by eating the bones, vitals, etc., of strong animals. The carcass of a full-grown tiger will sell for a hundred dollars or more; and I have seen men peddling tigers' skeletons at so much per ounce, for a tonic. But these, while very good, would not be equal, they think, to the human article, if any one cared or dared to prepare it. I have heard of Chinese soldiers even forcing themselves to eat the liver of an enemy killed in battle, to increase their courage, for they think the liver is the seat of courage.

A distinguished Chinese statesman and general who died last year is said to have lost a son in the following manner: This son had a piece of flesh cut from his arm to make a tonic for his mother, and bled to death in consequence; so there were those who affirmed that the peculiar potency of our foreign medicines is due to the use of human vitals in their preparation. This scandal, however, did not gain sufficient currency to make us serious trouble. There were a few Foochow women in the neighborhood, of bold manner, who came to see the foreign women, and brought numbers of the more timid women with them; and they were always shown all over the house, up stairs and down. By and by the wife of a beloved native helper, who had grown worse as her husband had grown better, had to be divorced. Her relatives made a big row about it; but it gave the finishing stroke to the medicine slander. It showed, also, that the wife of a Christian could not sin against her husband with the same impunity that a Chinaman could sin against his wife.

The truth slowly gains ground. The Chinese have long admitted that Western nations excel in the mechanical arts, but they have comforted themselves with the belief that they themselves excelled in manners and morals. Now the painful, humbling idea begins to press them that the followers of Christ excel in these things also; and their boasted Confucius must yield to a GREATER ONE. We try to make them understand that Jesus is not a Western sage, but the divine Savior from heaven who does for us what no sage can do; and that we are come hither, not to humiliate them, but to save them.

Foochow, China, May 4, 1886. J. E. WALKER.

CLIPPING QUEENS' WINGS 1900 YEARS AGO.

A TASTE OF VIRGIL.

I HAVE been clipping my queens' wings to control swarming. I got the idea from your A B C book, and, with some few draw-backs, it is good. I think I clipped the wings of some old queens, and they died off and left the swarm queenless. But what bothers me is, that you bee-men began the habit only of late years, since the improved frame hives have been in use; and I find, on reading Book IV. of the Georgics of Virgil, that the Italians used to clip their queen-bees' wings for the safe-keeping of a restless swarm. I quote a translation of his original Latin, from the 103d to the 108th verse, inclusive:

"But when the roving swarms fly about and sport in the air, disdain their hives, and leave their habitations cold, you will restrain their unsettled minds from their vain play; nor is there great difficulty in restraining them; do you but clip the wings of their *kings* ("*tu regibus alas eripe*"), not one will dare, while they (their kings) stay behind, to fly aloft, or pluck up the standard from the camp."

How did they, in his day, 1900 years ago, get at the queens to clip their wings, unless they had movable frames?

I feel compensated in thinking over the fact that he knew all that before we did, only in the other fact that the old poet did not know they were *queens* and not *kings*. JAMES J. SLADE.

Columbus, Ga., June 18, 1886.

If I render correctly from the Latin which you quote, Virgil does not recommend to *clip* the king's wings, but to *tear* the wings from off the king. The Latin word "*eripio*," of which "*eripe*" is the imperative, never means, so far as I can ascertain, to clip or cut, etc. However, the rendering which you give probably best conveys the idea to bee-keepers of the present day. At any rate, Virgil recognized the fact 1900 years ago, that crippling the queens' wings prevented, to a large extent, swarms leaving altogether. I think that Virgil meant that the bee-keepers of his day should catch the queen in the cluster after her bees had swarmed. This, then, would not necessarily imply that the Romans had movable-frame hives.—Many thanks for calling our attention to this matter of bee-history. Perhaps friend Hasty can give us another dish of Virgil upon this matter. ERNEST.

THE TENT FOR CATCHING SWARMS.

HOW MRS. AXTELL MANAGES.

DEAR FRIEND ROOT:—I want to tell your readers, especially the ladies who don't like to and can't well climb trees for bees, what a nice and convenient arrangement a mosquito-bar tent (referred to before in GLEANINGS) is to bring back virgin swarms—even the mosquito bar without the frame, as I have but one frame, and I use several cloths, or, rather, several tent-covers.

When bees begin to swarm, even if half are out, I set the tent over the hive; and if the bees are half out, the remaining ones make such a roaring that it calls those on the wing back every time. When all are out the hive that care to come, I lift the tent off to one side and open the hive; cut out cells in brood, etc. The bees outside of the tent and on the wing swoop down on to the combs. When the hive is closed I take off the netting by turning it wrong side out, as many of the bees stick to the cloth, and I shake them in front of the hive, and then the work is done.

If swarms from hives having clipped queens start to issue, and I have a swarm on the wing, I throw a tent or tent-cover over the hive, and kneel down close to the netting and look through and catch the queen and cage her, letting the swarm come and cluster on the tent-bars or to the projecting ends of the cover of the hive.

I have always very much dreaded my virgin swarms, as I take nearly the whole care of one apiary, numbering now 95 strong colonies and about 20 nuclei and weaker ones, and Mr. Axtell has the care of the apiary located near the timber, 4 miles away. I feel very thankful for the tent arrangement to catch the virgin swarms. I could not handle bees successfully, I fear, except the queens' wings were clipped, though I feel confident we sometimes lose a queen by doing so. One of those queens you sent was a beauty, and was successfully introduced on to hatching brood by brushing the bees down in front of hive and letting all old ones return. I left her caged over night, and released her on the brood. In a week I found the hive full of eggs, and a nice little colony. I clipped her wing. The bees had become old enough by this time to show their black spunk, and scamper like a flock of sheep. I then concluded I would never again choose black brood and bees for a choice queen, but my gentlest Italians. We had a few colonies that were very dark hybrids, and I wanted to get rid of them on account of being so hard to handle, and so poor honey-gatherers poor years, but they do make most beautiful honey, and carry it above, leaving the brood-nest for the queen. For those two traits I like them better than Italians in good years, as the present has been so far; but we have had no rain for some time, or but little, and the honey harvest may close early. Some colonies have given in from 50 to 100 lbs.

The Heddon slatted honey-board is a splendid arrangement to keep the sections clean; we use it both above and below the rack with a cloth over it above the rack, if the cover does not fit down closely. MRS. L. C. AXTELL.

Roseville, Ill., June 23, 1886.

HOW SHALL I MAKE MY BEES WORK IN THE SECTIONS?

A SPEEDY WAY OF GETTING RID OF THE FALSE IDEA THAT HONEY IS ADULTERATED.

I HAVE two colonies I wintered over. They came through in good shape. Each have 10 frames full (L. hive), from bottom to top with brood and honey, and the hive is almost full of bees. I have caps on with two crates each, holding 14 lbs. The bees will not go up and work in them. What is the cause? They seem to be busy on white clover and basswood, and there is an abundance of both. I put some half-filled sections in caps, which I had left over from last year. I thought perhaps it would induce them to commence in the caps. I looked next day and the cap was full of bees. I thought I should soon have two crates full of nice white honey. I looked again, four or five days afterward, and, to my surprise, I found no bees. On examination I found no honey in the section I put in. They had carried it all below, and have done nothing of any account since.

The basswood is now just in its full bloom, and white clover has begun to dry up. If they do not fill the caps pretty soon I shall not get any honey this season. How can I put them at work in the caps?

WHEN IS THE BEST TIME TO MOVE BEES?

I bought four first swarms. They came off the 21st, 22d, and 26th of May. They have filled ten frames full. I never saw bees build up faster in my life; but when they got up to the caps they stopped; nevertheless, they seem to be working very hard.

I commenced last season with three hives. I let a man have them to keep on shares. I will move them home this fall or winter. When is the best time to move them? If I move them before they go into winter quarters, will they go back to the old stand? I have to move them about an eighth of a mile. When I go to pack them up for winter, and it comes a warm spell so they fly, won't they go right back to their summer stand?

THE EFFECT OF THE FALSE STATEMENTS, AND WHAT TO DO.

I was talking with one of our leading merchants the other day in regard to the honey market. Said he, "I sold many a pound of honey for 50 cts. years ago." I asked him why it was he could not sell it now for half the former price.

"Oh! this *patent* honey has ruined the honey-trade."

"Patent honey?" said I.

"Yes," said he; "why, just up here at a little town between here and Indianapolis they are making nice comb honey. They make the comb by machinery, and then fill it with this patent honey, and cap it up and sell it for pure honey."

I asked him if he knew that to be a fact. He said, "Yes, sir; I see no reason to doubt it; Mr. B. told me so."

Now, Mr. Root, I made him this proposition: If he would show me the factory that made this patent comb honey, as he said they did, I would give him $100; and on top of that I would give him $100 for every pound they had on hand. He said he thought I would find it pretty expensive. I told him I would do just as I said. Do you believe I am safe? I agree with him in one respect; that is, the patent honey has helped to reduce the price of our product. There are people who would buy our honey if it were not for that notion of patent honey. I believe when we get that out of the way we can sell our honey at a better price, and find a more ready sale for it. What say you? J. M. TUCKER.

Clinton Falls, Ind., June 26, 1886.

Friend T., I feel quite certain that the reason why your bees do not go up into the surplus-receptacles is because the honey-yield is closing. With one or two sections containing combs partly built out last season, placed among the empty ones, they will be almost certain to go up if honey enough is coming in to make it advisable. The fact that bees have been once up in the sections in a cluster is evidence that they have started to work; and on account of cool nights, or a lack of honey, they have given it up.—It is quite a difficult matter to move your bees an eighth of a mile, unless you do it in the winter time, after, say, a lapse of two or three weeks of weather unsuitable for them to fly. They will go right back, as you say, if moved during the working season.—Sensational stories about spurious comb honey are, I believe, pretty much at an end. The low price at which honey is going to sell this season will have much to do in the way of discouraging such talk.

CONTINUOUS SWARMING FOR FOURTEEN DAYS.

A SWARM SCOOTS FOR THE WOODS, WITHOUT ALIGHTING.

MY bees kept swarming out every day for fourteen days; then it rained, and the weather cooled down and so did the bees. We had been having very hot and *very dry* weather for a month. After I had written to you about my "crazy bees" I went out and gathered up all the loose boards I could find, and put them on the hives to shade them; and when I ran out of boards I used a few chicken-coops that had a blind side to them. Then it came to me that Mr. Heddon used shade-boards on his hives, and I thought most likely he had a patent on them, and would sue me, and put me in the penitentiary for imitating them. But the shading did not seem to do any good. As fast as the other swarms (after the first six) came out I carried them to the deep shade of the European larches and gave them plenty of air, and they behaved. One of the bad six

WENT TO THE WOODS WITHOUT ALIGHTING,

Leaving the queen under the goblet. You ask why I did not divide the swarms. I answer, "Because that is not my method." I don't like bees; I keep them for the money that is in them, and I won't have a lot of semi-good colonies sitting around, nursing young bees that I care nothing for when the white-clover season is over. My bees have got to be booming colonies, and do business worth while, or I won't keep them at all.

Ernest says, on page 501, that it is because the child is unconscious of danger that it does not get stung, and that nervous people are apt to get stung, or words to that effect. Yesterday, when I opened a hive from which a swarm had just issued, to take out a frame of brood, two bees flew up and stung me, one on the eye, the other on the jugular vein. I thought I could get used to doing without a bee-hat and smoker. I had on a sun-bonnet, and I shut the fronts of it together, and walked to the kitchen, with dozens of angry bees flying around me, fired up the smoker, and made those bees dance. I smoked them for all that smoker is worth, and not another bee stung me. My arms were bare to the elbows, and *I was mad*. I am now going to treat my bees just as I used to treat "Jenny" the mule—always keep the upper hand—no patting, no favors.

I do not like those crates with glass in the side that I got of you. I do not like the closed-top sections; it makes the bees uncomfortably warm. I want crates that I can tier up five deep. I like Mr. Foster's section, with openings on every side. That is, I like the idea, and I am going to try them when I buy again. MAHALA B. CHADDOCK.

Vermont, Ill., June 19, 1886.

I am glad to know, Mrs. C., that you like the open-top sections. I presume the reason why so many object to them is because of the trouble of closing the openings. The closed-top sections, I presume you know, are already closed. I suppose the latter are more convenient for a colony that is not strong enough to need tiering up.—Haven't you got some hybrids among your bees, my good friend? and isn't this why they are so cross?

ANOTHER GOOD REPORT FROM ALSIKE CLOVER.

WHAT FIVE ACRES WILL DO.

FRIEND ROOT:—We have just had a good chance to test the merits of alsike clover, and it has done nobly. Our 5 acres, sown last season, for the past 5 weeks has been roaring with bees, and they are still working on it to some extent. The month of June, in the past five seasons, has been our discontent, and the hardest on bees of any month in the year—no white clover, no basswood, the spring bloom all gone, fighting and robbing all through the month. Alsike bridges a very bad place, besides the hay and pasturage we get from it. Nearly 100 colonies had access to our alsike, and our own 30 colonies increased to 66 by natural swarming. From one colony that did not swarm, we extracted a common water-pail full. Several others nearly finished their sections. All first swarms, and some after-swarms, have the hives full of brood and honey —not a swarm lost by absconding; gave all a frame of brood. The only swarm that tried to leave was a rousing big first swarm. It came right out of the hive, and, without clustering, "lit out." I followed them a mile and a half, waded a creek, climbed a tree, got 'em into the light swarming-box I happened to have when they "lit out;" brought them back, and they are now all right. Don't say it wasn't a *first* swarm, for it was, sure. Hurrah for alsike! M. F. TATMAN.

Rossville, Kansas, June 29, 1886.

HOW LATE SHALL WE KEEP WINTER PACKING ON THE HIVES?

MAKING CHAFF CUSHIONS FROM EMPTY PHOSPHATE-SACKS.

IN GLEANINGS for June 15, Mr. W. Z. Hutchinson speaks of the good effect of keeping bees packed on their summer stands till warm weather. Here, where we winter on summer stands, every farmer uses more or less bone meal, bone phosphate, or other fertilizers, and the empty bags of strong burlap are washed, and, before cold weather, wheat chaff, say one-half bushel, is put in, and it is spread evenly and closely over the top of the quilt for winter. They are easily removed for examination, and a use of these for years has proved very satisfactory. They are left on till I get ready to put on cases, and the protection is a decided advantage during the cold nights and wet days of spring.

One season I tried the experiment of packing hives with chaff all around the hive, and left them so packed during the summer, with a free entrance. They performed no better and no worse than others not protected, excepting top chaff packing.

One of the objections formerly raised by me to friend Heddon's "innovations" of thin sides for hives and cases, with no other joints than a planed surface gives, was the exposure to sudden changes of temperature. We know a high degree of heat is essential to comb-building; and we also know that, if that heat has to be supplied as it is by the consumption of honey, that it pays us to economize in the costly fuel, and protect, to save the waste.

It is to be hoped that experimental work this season will determine the value of the narrow L. hive.

If, as is now claimed, the contraction of brood-chamber to five or six frames during the honey-flow will prevent the accumulation of pollen, it will be a boon to many who are over-burdened with its accumulation in the brood-chamber. But here, when at times we have sheets of comb two-thirds filled with pollen, it disappears rapidly in the spring, to be replaced later by new pollen.

This shows its importance in the internal economy of the bee-hive. But at times it is a nuisance, and valuable brood-space is sure to be preoccupied, if, from any cause, the queen is not fecund and active.

The yellow capping mentioned in my last is evidently a trait peculiar to some bees. I am marking for a change of queens and stock, all that show it.

Our season is wet, and for the last two weeks we have had a decided improvement in the honey-production, and bees are booming. J. W. PORTER.

Charlottesville, Va., June 28, 1886.

Friend P., your suggestion is a valuable one. The phosphate-sacks are of exactly the right material, and they come so near being the right size I do not know why they will not answer about as well as any thing we can make. Our experiments of late have all indicated that it pays, and pays well, to protect the hive from both heat and cold while the bees are building combs and storing honey in sections.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

THE QUEEN THAT STOPPED LAYING.

THAT queen mentioned in my letter — page 485—commenced laying all right within three days after that letter was written. My guess now, and it is only a guess, is, that she had previously laid drone-eggs exclusively; and the little colony, having no use for that kind of increase, had destroyed the larvæ.

You have done a special favor to me, and probably to others, by telling your experience with Carniolans, though it is rather disappointing.

THE HONEY-JUMBLES.

Will you now please publish a recipe for making those honey-jumbles mentioned on page 460? It might be useful to families who do not live within range of your wagon. DAVID STRANG.

Lincoln, Tenn., June 21, 1886.

In regard to the recipe for making honey-jumbles, we have written to the manufacturers, and below is their reply:

We should not like to sell a recipe for our honey goods, as it would likely get into the hands of other bakers to our injury, as we pride ourselves particularly on the superior quality of our honeys. The recipe would be of little or no benefit to families, or any one working without machinery.

CRAWFORD & TAYLOR.

Mansfield, Ohio, June 29, 1886.

Now, although it seems to be true that jumbles exactly as good as those we sell can not be made in families, no doubt our women-folks, by a little experimenting, could make something near it. Another thing, if they are home-made they might be given to the children hot. I have always been a great admirer of hot cakes and cookies when they are first tumbled out of the oven. It seems to me they are nicer then than they ever are again afterward. After the friends have tested ours, and have tried their skill in making something like them, we will gladly publish recipes for making honey-jumbles. We can send four by mail, for samples, in a pasteboard box, for 10 cents.

A FEW QUERIES; ALLEY TRAP, HONEY-DEW, ETC.

Bees are booming on clover and honey-dew, which is the first I have seen here for 12 years. It is very plentiful some days, but we had a good rain to-day which will perhaps put an end to it. If you will answer the following questions in GLEANINGS it will greatly oblige me, and possibly many others. How can we tell honey-dew honey from other honey? Have you yet captured any queens in the Alley trap, and hived your swarm without climbing and cutting it down? In other words, does the trap pay? is it a success in hiving? In regard to the Alley queen-nursery, can we raise queens with them by cutting out any extra queen-cells we do not need in other hives, and placing them in the nursery and keeping them in the center of any good hive? If so, how long can they be kept in the nursery? and how about fertilizing them? Now, I have 50 hives. I want to keep from 60 to 80 swarms, but always find five or six hives queenless every spring. Will it pay to try to raise and keep a few queens on hand, or is it best to put new swarms in these queenless hives?

W. H. RITTER.

North Springfield, Mo., June 16, 1886.

Honey-dew can be detected in sealed combs by a dark shade of color which it presents under the cappings. By holding the section or frame of capped honey between you and the light, the difference in color between the honey-dew honey and the clover or basswood is so great the bad portions may be cut out with a knife; the rest can then be used for table use. Even a single cell can be detected in this way. Other dark honey may present a similar appearance, but the surest test is the taste. If you once get a drop of the pure stuff on your tongue you will never forget its sickening flavor.—The Alley trap has been used very successfully by us. See department of Our Own Apiary of last issue, and also page 461, current volume.—If I am correct, Mr. Alley designed his queen-nursery for the very purpose of keeping extra queen-cells. See page 23 of his book on queen-rearing. After the queens are hatched they are to be given a queenless colony, which we do by simply letting them run in on the frames. The queen will then be fertilized in the ordinary manner, if she be accepted by the bees, which she is, in the majority of cases, with us. We use, however, and prefer, the lamp-nursery described in our catalogue, for hatching young queens, to the one used by Mr. Alley.—You could probably raise your own queens if you have a good queen to breed from. You will find your questions more fully answered in the A B C book.

THE DANGER OF LEAVING QUEEN-CELLS IN A COLONY WHERE A QUEEN HAS JUST BEEN INTRODUCED.

A most peculiar misfortune has happened to me in regard to a queen I bought of you, as follows: June 9th I received an untested queen from you, which I immediately introduced to a colony I sold a few days before to a friend. The colony having swarmed before this time, I cut all the cells out and put a piece of larva in. On Sunday, June 13, I looked in and found the queen all right; but on the larva they had started some queen-cells which I supposed the new queen would destroy, and so I did not touch them, but put on the upper story, supposing every thing was all right. This morning, the 22d, I found the queen dead before the entrance. On looking in I found that your queen had filled several frames with eggs, some frames having brood ready to seal. On looking further I found a *hatched* queen-cell on the piece of larva, and also a small unfertilized black queen which would have come out only yesterday. Does this happen often? and why does the queen not tear down cells? I found the other queen I bought of you doing so. As this hive belongs to a friend who does not know much about bees, he might accuse me of knowing nothing of bees, and say it was my fault.

G. WIEDERHOLD, 11 12.

Yonkers, N. Y., June 22, 1886.

Friend W., as a rule the introduced queen will destroy the cells, but there are occasional exceptions, like the one you mention. They are so rare, however, that we seldom take the trouble to destroy the cells unless the queen is one of special value.

SHALL WE PRACTICE ARTIFICIAL SWARMING?

My bees do not swarm as I think they should, so I tried artificial swarming on one and have a good young swarm from three frames of brood; but the process is too slow for me. I swarmed them May 30th, and can't expect the queen to lay before June 20th. Would it not pay better to buy queens to start with? I am using the American hive, but I do not like it. What hive do you recommend for a beginner?

E. T. CASE.

Nunda, N. Y., June 18, 1886.

Friend C., the matter you mention is so fully discussed in the A B C book I do not think it is best to take space to go over it here. Circumstances must determine whether it is better to buy queens or raise them. The fact that the Langstroth frame is so universally in use would be a sufficient reason for adopting that in preference to any other, and I certainly think it gives as good results as any other.

A FIVE-CENT PACKAGE OF COMB HONEY.

Since trying the 1⅝-inch sections in crates, I am so well pleased with them that I think I shall henceforth use them almost exclusively. The combs are as nice and straight as I have ever had them, even with separators attached; and as they do not hold so much they can be retailed for 15 cts. or less, and a great many more can be sold. Dealers say, if they can not get any thing so as to sell it cheap, they do not want to handle it at all. If the people want small packages, and are willing to pay the difference in price, why shall they not have them? I have long thought (and do not know but that I shall soon try it) to have comb honey in five-cent packages, so as to take the place, in a measure, of the filthy candies. The way I should try would be to have a nice thin comb built in a regular frame, and have little tin sections, or something of the like, and just press them in and let the bees fill them. But may be some one has tried and abandoned it, long before I was a bee-keeper, though I became one not many years ago, when I was only six years old.

CHRISTIAN WECKESSER.

Marshallville, O., June 21, 1886.

Friend W., this matter has been pretty thoroughly discussed. I do not think you want any tin at all about your sections. It does not answer well, and it strikes me we had better not undertake making a package of comb honey at a less price than a dime: and I believe that many experiments seem to decide the best way to do it would be by having a thin section. Make it the standard size, 4¼ x 4¼ inches, but let it be thin enough to hold 10 cts. worth. Perhaps ⅞ inch, the width of our brood-frames, would be about right. In selling sections of honey at a uniform price, the difficulty seems to be in having them all alike. If they are made thin, as above, of course we do not want to use separators; and the result will be, that some will be heavier than others. Perhaps it would not matter if they were. We are now getting 18 cts. a pound on our wagon for extra nice white comb honey in sections. They are seven to the foot in width, and the price runs from 15 to 18 cts. Since you suggest it, I firmly believe that a ten-cent package of comb honey is going to be a big thing. On our wagon we endeavor to have goods sold at 5 and 10 cts., even change, as much as possible.

WHY IS IT THAT MY BEES DO NOT DO AS WELL AS MY NEIGHBOR'S?

Now I wish for a little advice about my bees. I commenced the season with 5 colonies, and have increased so far by swarming, to 12; but they haven't made a pound of surplus honey, yet there is a plenty of blackberry and raspberry flowers here, and it seems as though they could do better. My hives sit on a level place, on good sawdust mounds, all in line, ten feet between hives each way, and close to a nursery of young apple-trees. They all face the east, and are in Langstroth hives.

BOX HIVES VS. MODERN BEE-KEEPING.

Last summer I got from one hive about 20 one-pound sections of surplus honey, which is the highest I ever got from one hive. I hardly ever average more than 5 lbs. to the hive, while only two miles away from me, in the same valley, a man who has about 40 colonies has already taken off nearly 400 lbs., and expects to make about $400 or $500 from the 40 or 50 colonies. What is the matter with mine? He keeps his hives on stands about two or three feet from the ground, and the bees he keeps in old-fashioned square box hives. If you can give me any advice on the subject, I should be very much obliged to you. I have never yet made enough to pay for the time I spent among them, to say nothing of the expense of the hives. I wish to make something on them if I can.

W. H. PRENTISS.

Prentiss Vale, Pa., June 21, 1886.

I think, my friend, that the hives or the way in which they are fixed has little or nothing to do with the amount of honey received by you and your neighbor; for although he is only two miles away, there may be a very great difference in the locality. This is easily shown by planting hives at different points in your immediate neighborhood, say from two to five miles apart. You will find that some will do a great deal better than others.

SPACING THE FRAMES TOO FAR APART.

I know you must be very busy while this enormous honey-flow is going on; but I must ask one or two questions. May 21st I put a primary swarm in a Simplicity, with 9 frames equally spaced, save two, they being too close. I covered them with new canvas, glossy side down. June 3d, 13 days afterward, I found the cloth being adherent, seven frames filled, other two partly, but many of them strongly bridged across. First, is there any better cover than what I have? Second, must I tear the frames apart? WM. S. ADAMS.

Queenstown, Md., June 7, 1886.

There is no better way than to tear the frames apart, cut out the combs, and make what use of them you can, and start the bees right. The use of comb foundation would have saved all your trouble.

SYMPHITUM ASPERRIMUM (COMFREY).

This has been advertised as something wonderful for honey-production and fodder-production, *100 tons to the acre*. This is an old dodge, 40 or 50 years old. I don't think a fact can be produced to show where it yielded 10 tons to the acre, or where any animal relished it as food, unless it is brought to eat it by starvation.

THE RESURRECTION PLANT.

You will not often succeed in making the resurrection plant grow. The only way to do so is to get it as soon as possible, as gathered in its native home, and then do not soak it, but lay it on moist soil, covered with a bell-glass or tumbler, shaded, so it revives by degrees. This soaking full of water, and exposing to the air at once, won't do it. If you take immortelles and dampen them they will shut up; put them in the sun, and they will open almost daily; and so with helychrysum, rhodanthe, and so on. F. J. M OTTO.

Sandusky, O., June 21, 1886.

SPANISH-NEEDLE HONEY.

Your comments on the article of T. S Robbins, in GLEANINGS of June 15th, led me to believe I could make a sale of some fine Spanish-needle honey to you next fall. We *never fail* to get a large crop. I have 30 hives arranged for extracting, and can pack in 1, 2, or five gallon jacketed cans. What can you offer for it per pound, f. o. b.? We are now harvesting a crop of fine clover honey —4600 lbs., from 100 colonies (comb honey). We always winter on summer stands, with Spanish-needle stores, and have very few losses. Last winter (a severe one) we did not have a single loss nor a single case of dysentery. E. BURKE.

Vincennes, Ind., June 19, 1886.

Friend B., we are at present so well supplied with honey that does not sell, that we could not promise to take any more. Perhaps some of the friends who see this will be able to take it off your hands.

WHY WAS IT THE COLONY WOULD NOT BUILD QUEEN-CELLS?

I have 14 colonies of bees, some bright Italians, and some mixed. I am in the flooded district. At the time of the flood here I had to move my bees twice, losing many by confinement, and some by falling in the water. I began building them up after getting them home. Two were queenless and weak. All built up well, as all had honey enough. May 8th, I had two natural swarms. I divided one, and started two nuclei with four frames each, with plenty of brood and eggs. Neither of them made an effort to make queen cells. I gave them each another frame of brood, with the same result. This I have done four times, as fast as the cells were sealed. On the 19th I examined them again; no queens, but bees plenty, storing honey and pollen. I have given one of them the fifth frame with three queen-cells closed, and one cell still open. Can you tell what is the matter? They are not storing much surplus, for out of 22 days it has rained 20, with a cloudy prospect for more. S. J. SMITH.

Chattanooga, Tenn., June 21, 1886.

I can not tell why those two colonies refused to build queen-cells, unless it is because they have some sort of a queen in their hives. Once in a while a colony gets a queen that does not lay, and they will very often hold on to her until they are rendered worthless. The only way to make them build queen-cells is to hunt them out. Introducing a laying queen would be the best thing, but they would probably refuse to accept a queen if it is as I have suggested.

REPORTS DISCOURAGING.

AN ADVERSE REPORT FROM TEXAS.

BEES have done worse this season than I ever knew before, one-half of them having starved to death. They commenced in March, the prettiest I ever saw, and raised a large amount of brood, and I was sure I should have a great many swarms by the 1st of April; but about that time we had a heavy frost that destroyed the bloom, and cold, continued rains until the 25th, and then it set in dry. We had no rain until the 18th of June. With such unfavorable weather we had no new swarms, and I don't think there were over half a dozen swarms in this whole section of country. I don't think that, in my 100 colonies, from the 1st of April to the 15th of June, they gathered over 10 lbs. of honey. They came through the winter rich; but on account of raising such a large amount of brood, and such unfavorable weather, they could not swarm. They destroyed their queen-cells, and clustered on the outside of the hives, leaving the impression they were going to swarm, until they ate up all their stores, then they began to starve to death.

About that time I was very busy cutting hives for myself and neighbors, leaving my wife to watch when they commenced swarming. By that means I neglected noticing them until I heard my neighbors complaining of their bees dying, then I began to examine, and found mine in the same condition. Then I commenced feeding, and fed 175 lbs. of sugar, but lost 10 colonies, from which you see it almost blasted my hopes and discouraged a great many beginners in the business, some of them losing all they had. What are left, however, are now doing very well, and the outlook is favorable. I am satisfied the Cyprians and Syrians are the bees for *this* country; for while the Italians and blacks give it up and quit raising brood entirely, the Cyprians and Syrians never stopped, and came through the drought strong, and are now working vigorously, while the others are just building up.

Notwithstanding the great disaster that has befallen the bee-industry in this section, I am not dispirited, and my faith is as strong as it ever was. I expected a great many swarms this season, and prepared to hive the increase; consequently I have about 100 extra hives on hand, and 80 lbs. of foundation, which I shall have no use for this year.

Gatesville, Texas, June 24, 1886. M. SIMPSON.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from June 15.

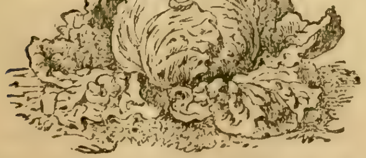
CHAPTER XIX.

If ye be willing and obedient, ye shall eat the good of the land.—ISAIAH 1: 19.

I have before mentioned, incidentally, the importance of selling our crops at a good price after they were raised. To do this, as well as to do any thing else well, the heart must be in it. The text above strikes at the root of the matter—you must be *willing*. Your work must be a pleasure and not a drudgery.

One of the first things to sell is lettuce. After we sold out our crop of lettuce from the greenhouse, by a little bad management we had no nice lettuce to offer our customers for some little time. Finally, however, here and there a head began to be suitable. What fun it was to see them improve and enlarge in just 24 hours! Yes, I learned to see a difference in the heads between morning and night and between night and morning. What fun it was to go over the whole plot and carefully pick out such as would answer, until we could say, "There, I guess there are about as many as the boys on the wagon will dispose of to-day." They start out at six o'clock. When they get home at noon one of the first things to inquire about is, "Did you have enough lettuce?" Sometimes the reply would be, that it just went round, and that was all; at other times, "No, we did not have half enough. Why, it seemed as if everybody wanted lettuce to-day."

By and by the heads began to fill up faster; and wasn't it fun to get a great basket full that were just right! All of the good heavy ones we got a nickel apiece for; smaller ones, two for a nickel; while those that weighed a pound or more would readily bring ten cents. A little later, and some of the Boston-market lettuce-heads began to show symptoms of wanting to send up a seed-stalk. As this Boston-market lettuce is one of the staple sorts, especially for greenhouses and cold frames, I will give a cut of it here, which is kindly loaned me by Peter Henderson.



BOSTON-MARKET LETTUCE WHEN IT IS JUST READY TO CUT.

When the heads begin to burst and to send up a seed-stalk, the matter has changed. Instead of rejoicing to see the growth made each 24 hours, we begin to wish they would not grow quite so fast, until we could sell them off a little. Mr. Bushnell (who is, I think, the oldest one among us) began to tell me that I was going to lose some of them because they would burst and start up to seed before we could possibly dispose of them. I told him to just let me do the gathering, and I thought I could fix it. The next morning I went over the whole patch, and counted to see how many heads there were that would have to be gathered that morning. Then I cut all that would not possibly bear to stand another day. After this I cut the next worse, until I got as many as they could possibly sell. Then I spoke to the men on the wagon something as follows:

"Boys, if you can manage to sell all these heads of lettuce to-day, I think we can take all to-morrow morning that will be so far along they must be cut, and so on. Now, suppose you make a little extra effort to *push* the lettuce, even if you don't sell so much of something else, that we may avoid losing any."

What do you think the result was? Why, the first thing when they got home was to tell me, "Mr. Root, we sold every head of your lettuce, and could have sold more too if we had had it with us."

The next day I did the same thing, and so on, keeping ahead of the ripening until we had a little shower. Then Dame Nature was too much for me—the heads suddenly burst open—a great number of them.

Let me here digress a little, to say that I had for some time had my eye on certain heads that I wished to save for seed—some that had made great big hard heads which remained a great while, ready to cut, without bursting open at all. Now you can readily see that, had my whole patch been like these few choice heads, it would have been a great help indeed in working off the crop. Not only this, they got so large and heavy before they burst that we readily obtained ten cents each for them. Well, after the shower I put stakes about these choice heads, marking them "For Seed," so nobody would make a mistake and cut them. Then we cut all the others that would not bear to be left in the ground an hour longer. We put as many on the wagon as would probably be sold by offering two pretty good-sized heads for a nickel. The rest we placed in the cellar, right on the damp ground. Lettuce can be kept one or even two days in such a place without any apparent wilting. It is better to cut them then than to leave them in the ground; for the sunshine after the shower would cause them to shoot up very rapidly; whereas, if they were cut off and laid in the cellar all this mischief would be at an end. By this kind of careful management our whole crop was worked off at an excellent profit; whereas, had the work been done carelessly by some one whose heart and soul were not in it, it might not have paid expenses.

Do you urge that it was not using our customers right to push things? I admit, that this might be carried to such an extreme as to be injudicious or wrong. But right here comes a point in regard to selling things. People very often buy that to which their attention is particularly called. We have two good salesmen on our market-wagon, and a small boy to do errands. A few days ago said small boy gave me quite an important fact. We happened to have a good stock of peas at the same time that we had a good stock of strawberries. Both needed pushing. Said the boy, "My pa can sell peas at almost every house. Mr. Weed can't sell peas, but he can sell strawberries at almost every house." Now, the probabilities are that we have many customers that have about so much money to expend for dinner, and it does not matter very greatly to them whether they have peas or strawberries. One man had got started in selling peas, and it came easier for him to make sales with them than with strawberries. With the other it was the other way. Of course, people should be allowed to purchase what they wish; but at the same time we all of us unconsciously influence people more or less with whom we have to deal. Let me give an illustration:

Some years ago, when we had a counter store on the fair-ground, I was a good many times greatly surprised that a thing which I expected would sell wonderfully, did not sell a bit, and *vice versa*. For a while I could not understand how my judgment was so much at fault. An incident gave the explanation. During quite a rush of business there was a complaint made that they were short of help. I accordingly asked my brother-in-law, Neighbor H., to please "lend a hand." This he did willingly, for he is a great fellow to talk and visit. We had just received a fine lot of stereoscopes, and the price was exceedingly low. I expected that, on the fair-ground, we should sell a great many. To my surprise, the clerks informed me that the stereoscopes did not sell a bit. Neighbor H. took a fancy to the stereoscopes, and before I knew it he was selling them to almost every man, woman, and child that came along. Another clerk was selling great big retinned dish-pans to everybody he traded with, and all went away satisfied, and a good many declared their purchase was exactly what they had wanted for a long while. It worked something like this: One of the clerks who didn't care much about stereoscopes would show the instrument in an indifferent way, not mentioning that it was very much lower than they had been sold; and I shouldn't wonder if he sometimes omitted to tell the price at all. A customer would say, "Oh, I guess I don't want one to-day." Now, Neighbor H. would tell so much about it, and show it to such good advantage, that the bystanders were interested; and perhaps he would set some of the children to teasing papa to get an instrument, with a lot of those pictures, to keep in the parlor, etc.

Now just one more illustration, dear reader, in regard to this matter of selling your products; for indeed it is so very important a matter I hope you will excuse me if I refer to it again and again. A few weeks ago we purchased a barrel of honey-jumbles—a nice little cake sweetened entirely with honey—no sugar or molasses entering into its composition in any shape whatever. I was very anxious to have these introduced in our town, and introduced generally, because of the opening it promised to dispose of the surplus honey now in our markets; and I thought I gave the boys on the wagon special directions about showing and explaining what the cakes were made of. I was considerably disappointed, howerever, to find they did not go off very well. A few days later I did not see the glass case containing them on the wagon at all. I asked the driver for an explanation. He replied that they were out in the rain one day and got wet, and so they ate them up, what there were left. The rain water made the case untidy, and so they sent it down into the kitchen to be washed.

"But," said I, "aren't you going to carry them any more?"

He replied that they didn't know whether

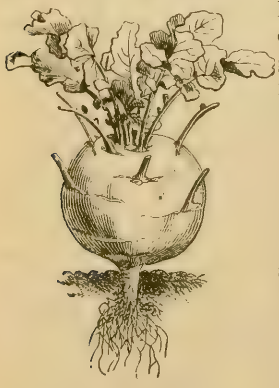
I wanted them kept on the wagon any more or not. Now, if there is any thing in business that vexes me, it is to find that our boys or girls have dropped something, or pushed it away out of sight, and let it go; and then, when questioned about it, say they did not know I wanted it used or kept in sight any longer. I could not believe that the honey-jumbles would not sell if properly introduced; so I sent to the manufacturers for *10 barrels;* and then I explained to all those who went with the wagon that I wished them to take them to every house, tell the folks what the cakes were made of, and see if they could not get them started. What do you think the result was? Why, they sold *16 dozen* the first forenoon. The next forenoon they sold *18 dozen;* and in about a week they had sold *four barrels* out of the ten. It is true, I reduced the price from 10 cts. a dozen to 8 cts. a dozen; but I am sure that giving them a fair showing had more to do with it than lowering the price. Do you see the point, you friends who till the soil, and raise honey or any thing else for sale?

Where a crop is going to spoil, there is no harm at all in using a little extra pains to sell as much of this as possible, in place of something else you are short of. If the lettuce is nice, there are few families where it will be wasted or thrown away; and it is relished by more or less people at every season of the year; but if your salesman is indifferent, or tired out, you may lose a great part of your crop in consequence, so you must keep an eye out for such contingences. Do the same thing with your radishes; and when raspberries and strawberries come, dispose of them in a like manner. Green peas are one of the great staples in market-gardening. Plan so as to allow nothing to go to waste, and have each article presented to your customers in the best possible shape, fresh and attractive; and this brings us to Chapter XX.

CHAPTER XX.

He that shall endure to the end shall be saved.—MARK 13: 13.

Not only will the man who patiently and faithfully endures, be saved, but he will be prospered here in this world. How many, many give up because, for a time, circumstances and conditions seem to be against them! When we first started out our market-wagon it was a thing so new and unheard of here that quite an opposition was raised to it. The grocers said it was not fair to go around to people's houses and catch their customers, and take away their trade. Men who had done a very little in the way of gardening thought that it was not fair that I, with my many resources, should break down their business by raising garden-stuff when I was not obliged to do it to get a living. Others thought the idea was ridiculous, that we could here, with our Medina clay soil, compete with the quality of the produce from Cincinnati and other great market-gardening points. Well, for a time it seemed as if there were some reason in all the above positions. People laughed at our produce, some of it; others refused to look at our stuff at all, because they thought we were not using the grocers right. A third said they never saw us have any thing nice. When we raised lettuce in the greenhouse, and put it on the market in February, they wouldn't buy it, because, they said, nobody wanted lettuce in February; and we were finally obliged to send a large part of our crop to Cleveland, where we got *25* cts. per lb. by the barrel for it, instead of trying to peddle it out on the streets here at home at only *20* cts. per lb. Well, I didn't give up, for I knew, or thought I knew, that people would in time be educated to these things. Last year they wouldn't buy cauliflower, because they didn't know what it was for. Somebody finally discovered that it was good to make pickles, and we sold pretty nearly our whole crop at pretty fair prices, to be made into *pickles.* This year we started some kohlrabi-plants in the greenhouse; and during the month of June we had quite a lot of beautiful bulbs ready for the market. The boys suggested that the vegetable would not sell, because nobody knew what to do with them. Perhaps I should add, that our wagon this spring has been getting to be a little more fashionable; that is, the nice vegetables we have been sending out "talked" themselves, and won their way into many new homes. Well, to my great surprise the kohlrabi very soon got a footing. It is true, that people did not know how they were to be cooked—a good many of them—and quite a number had never seen or heard of such a thing; but they had got into a sort of way of thinking that whatever we carried was good, if it were cooked right. Ernest's wife thought she would try cooking them as we do vegetable oysters, and they declared them to be "just splendid." Young married couples are a good deal inclined, you know, to call every thing "just splendid." Other folks cooked them as they do turnips or mashed potatoes, and they proved to be "splendid" that way. Pretty soon the kohlrabi-bulbs were called for a good deal faster than they grew, and we didn't have any trouble with overgrown ones. People called for them when they didn't know what the name was. One individual, after trying in vain to hit the name, said he guessed they called them "Kohl Abrahams." I could not think for quite a while where he got hold of "Abraham" until I remembered that Abraham was one of the greatest of the patriarchs, and a patriarch was often, in old Bible times, addressed as "rabbi;" or, at least, their descendants were so called in Christ's time. So our friend knew that it had something to do with patriarchs, and "kohl Abraham" was as near as he could get. Another customer wanted some "*Arabs*." Of course, he got what he wanted. We sell two bulbs for a nickel. What do you suppose an acre of ground would amount to with a good crop of kohlrabis sold at the above price? And, by the way, we can put kohlrabi on the market without trying very hard, before you can get cabbage, green peas, turnips, or any thing of the sort. Raise the plants indoors, just exactly as you do cabbage-plants. Plant them out in good rich ground; and before a cabbage would think of making a good head, these kohlrabis will have made beautiful bulbs. As some of the friends may not be familiar with this member of the Cabbage family, we give a picture of it. They must be used when they are, say, the size of a good fair-sized apple; for if allowed to grow very large they get woody and stringy.

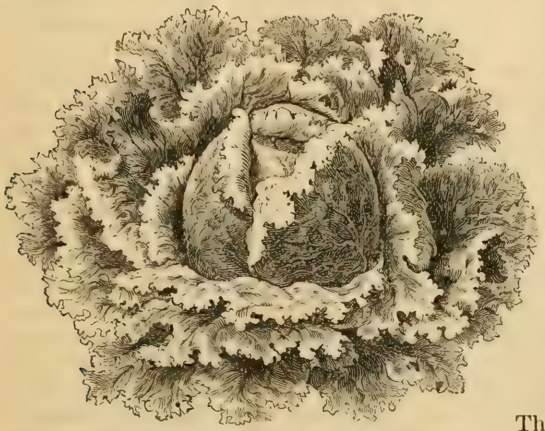


KOHLRABI.

SOMETHING ABOUT SAVING YOUR OWN SEEDS.

Now, a point comes in here that I want to talk about a good deal; in fact, I shall talk about it all through this book. I told you about marking the best heads of lettuce "For Seed." You want to do the same thing with kohlrabi, cabbage, and almost every thing else. Do you want to know why? If you could go to our kohlrabi-patch to-day you would notice that here and there are plants that are not going to make kohlrabi at all. Some of them look as if they hadn't quite decided what *to* do. One starts to make a cabbage-head; another has evidently got a mistaken idea that it was planted for a turnip, while a third is clear off from the track and is trying to put up a bunch of blossoms like cauliflower. What is the trouble? Why, the seed has not been carefully saved from choice specimens. The type of the plant has not been fixed by careful selection for many generations. You may say that I didn't purchase my seeds from a reliable house. Well, I got the seed from Peter Henderson or Landreth & Sons—I am ashamed to say I can not now tell which, and there is where I am to blame. You should know just where you got the seed for every thing you raise. Better still, you should raise your own seed, if it is a possible thing. The first kohlrabi that made a nice bulb should have had a stake put up beside it, labeled, "For Seed." Right here the interesting point comes in, that I do not know how they get seed of kohlrabi. I am going to find out, though.

There is an excellent little book published by Mr. Francis Brill, entitled, "Farm-Gardening and Seed-Growing." This tells us all about how to raise seeds of almost all our garden vegetables. Now, then, if I had for several years raised my own seed from none but choice bulbs, I myself could have fixed the type of our good friend "Kohl Abraham" (?) so that he would know just exactly what I wanted him to do when he got to the proper age to make a cabbage-head, a turnip, a cauliflower, or a kohlrabi. Our best seedsmen aim to do this; but, my friends, with the best intentions in the world it is next to impossible for all large seed-houses to have every seed they send out selected from none but such nice specimens as you and I can produce in our own gardens. It is the same with cabbages. We are now picking daily the prettiest little heads (almost as hard and heavy as a turnip) from our patch of 2000 early cabbages. Now, while the majority are of heads like these, quite a good many are making no head at all. They don't quite understand what is wanted of them, and so they are just acting foolish, and are of no use to anybody. They remind me of some boys and girls I have seen in this world. With the cabbage it is the fault of the parents and the early training; and I am afraid it is true, too, with foolish boys and girls — it is the fault of the parents and early training. Now, I have never raised cabbage-seed, and I don't know what I can do; but I am so well satisfied of what may be done that I would give to-day ten dollars for the seed of *one* cabbage-head in that patch of 2000. Do you want to know why? Because it commenced making a head almost as soon as the plant was taken from the greenhouse and set in the field, and a beautiful little head, too, hard and firm, and ready for the market fully *two weeks* ahead of any other plant in that field. The books on seed-growing say that this cabbage-head must be kept over winter before one can get seed from it. Well, it was raised so early I am afraid it will be a hard matter to keep it over winter, but I am going to try hard. I think I can get some sprouts from the stump, to raise some more heads later in the fall, that will give me seed next year, if I can not get seed from this one. Doubtless some of the older heads will smile to see me come out in print and confess my ignorance. Never mind, dear reader; let them smile. I have been "smiled at" a good many times in my life; but the ones who did the smiling at first, often smiled in *surprise* a few years afterward. Seed-growers have great difficulty in fixing the type of their seeds, I well know; and when a new and superior seed is placed before the people, the growers are entitled to a good reward. And this reminds me that, after our Boston-market lettuce was sold and gone, we had arranged for a succeeding crop of Henderson's new "New York" lettuce, as he calls it. This lettuce not only produces immense heads, but it is remarkably slow about shooting up to seed. Great nice heads will stand for many days waiting to be picked, and the quality is equal to any thing we ever had. It is a large late lettuce, so it probably will not answer as well as for greenhouse culture. As this "New York" lettuce seems to be quite an acquisition, we give a cut of it.



PETER HENDERSON'S NEW "NEW YORK" LETTUCE.

This lettuce makes wonderfully large heads. It is nothing to have them weigh from a pound to a pound and a half; and the inside of these great heads is as white and crisp and nice as celery. As it is not at all bitter, I have often eaten a whole head with great relish while out in the fields. Although it is very slow in sending up seed-stalks, we find somewhat of a tendency to rot, unless it is cut, say, in a week or ten days after the heads get fully grown.

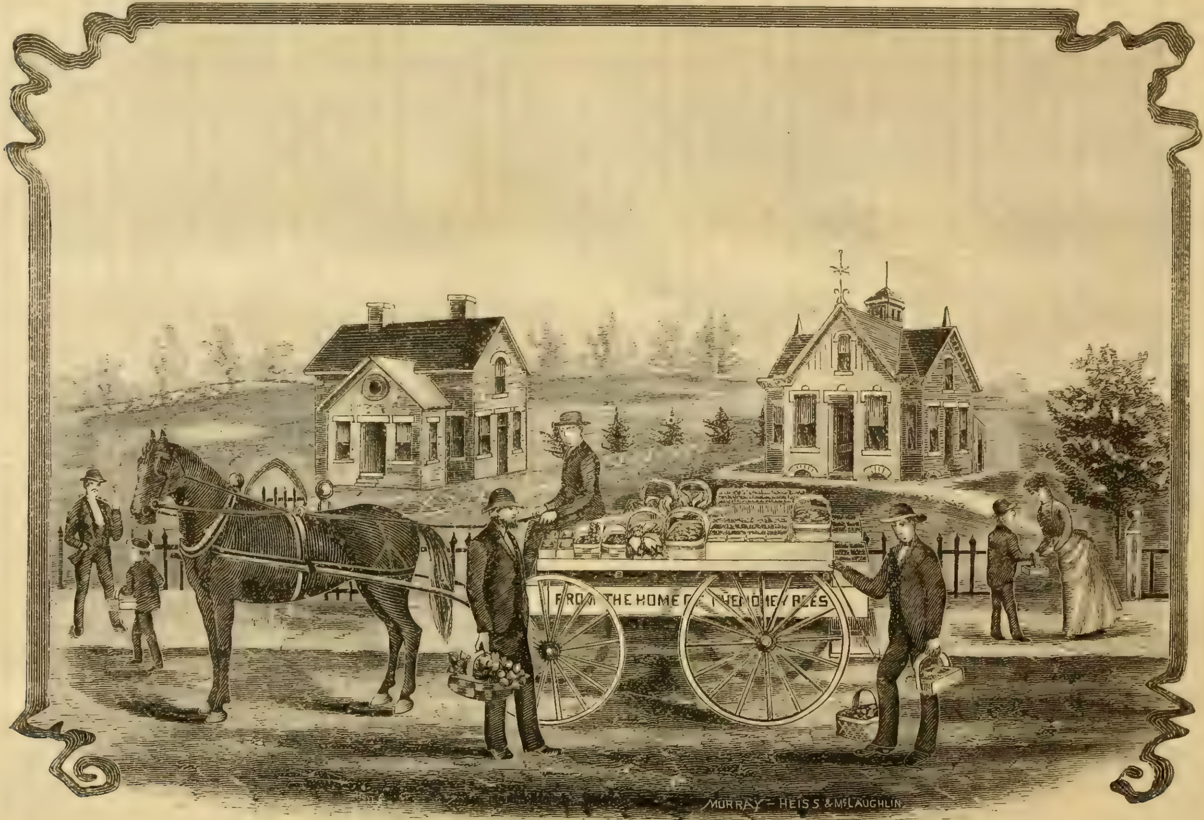
In the fore part of this chapter I mentioned the prejudice that existed toward our market-wagon when it first started. Well, notwithstanding this prejudice, and notwithstanding it did not at first pay expenses, we kept it going right along day after day, and even during the winter: when the roads were suitable we went with either wagon or sled. In the winter time we carry apples, turnips, potatoes, parsnips (when the weather is suitable to dig them), vegetable oysters, winter squashes, celery, etc. When the roads were too bad to go with a single horse, we sent out a stout double team, one that is generally used for plowing, drawing manure, etc. Going out under unfavorable circumstances during bad weather occasioned criticisms again, because people generally could not understand why we should stir ourselves so much for so little trade. My purpose was, to give them to understand that the market-wagon expected to be a regular institution, and one to be depended upon. Well, it seemed for a time as though prejudice was so great I should have to give it up; but I have found the little text at the head of our chapter true in business matters as well as in spiritual things. A writer on the management of horses once said, if a horse disobeys you, strike him one good smart cut with the whip—just one and no more. When he disobeys you again, do the same thing. Show no resentment and no anger, but simply give him to understand by many repetitions that disobedience brings pain. By no means let him see that you are angry or mad. Teach him to think you are a machine. In a little time he will learn to obey as a matter of course. The same process, it is said, will cure a kicking cow. Be sure, however, that you do not talk loud, or yell at your dumb friends. Now, humanity, in some respects, is like a dumb brute; at least, there is more or less *animal* about all of us. If community gets prejudiced against you, don't talk, or make a big fuss. By no means get to talking loud, or yelling about it. Go ahead in the course you think is right, as if you were a machine, and teach them that unkind words or prejudice has no more effect upon you than it would have on iron and steel. *Endure to the end.* Let them know that your endurance is like iron and steel; that is, a quiet, patient, kindly endurance. By and by they will drop it all and forget it all; and when they discover that you are not going to adapt yourself to their notions, they will, *if you do your duty*, adapt *themselves* to *your* notions.

I was a little amused, a few days ago, to hear Mr. Weed say that I had no conception of the feeling that was growing up in favor of our home-grown stuff, compared with that which came from the cities. He said it was getting to be so, that, no matter how nice an article he offered, the question was, "Did you raise this on your grounds, or was it shipped from the city?" If he told them it came from the city, it was handed back: if it was our own production, it was taken at once, without any further question.

Yesterday we had a fine lot of nice "Jersey Wakefield" cabbages that were purchased from the city, because our supply ran short. We ordered the best that could be found in the market, and got them. When the boys got back they said they had an order for two of our best *home-grown* cabbages. Nothing was said in regard to price; they must have some that grew on *our* grounds or none at all. Our wagon has not yet been running a year. Probably one thing that has contributed this spring to capture public sentiment is the fact that a great deal of our stuff is gathered in the morning, before six o'clock. Our customers get it fresh with the dew of morning still on it. Raspberries and strawberries are often picked, and sent by a boy to catch the wagon; and the small boy before mentioned, who accompanies the wagon, comes back almost every day with an order for "half a dozen more lettuce—more kohlrabi—25 winter-cabbage plants—6 quarts of strawberries, to be left at Mr. ——'s at exactly three o'clock," etc. The difference between things absolutely fresh, just gathered, and those that have been standing by the door in front of the grocery store for one or more days is a big point. While strawberries were selling on the street at 6 and 8 cts. per quart, we received 10 cts., for fresh ones right straight through the season. In fact, we have not sold a quart for less than 10 cts., unless it was some that were left over; the same way with raspberries, and the same way with peas. Inquiry is even made as to whether the *new potatoes* we carry around are raised by us or bought; and, by the way, I want to say a word in regard to

NEW POTATOES.

Some time about the 15th of April my wife informed me that some potatoes in a large pail in the cellar had sprouted to such an extent that they bid fair to make a huge bouquet, only the bouquet was composed of leaves and not flowers. I took them at once to the field to plant. Mr. Bushnell said I might as well pull the sprouts all off, for they would die anyhow. I told him they would not die after I had got them fixed. I chose some mellow sandy loam near where they were sowing parsnip-seed. I pulled the potatoes out of the pail myself, separated the roots, and then cut them, *a la* Terry, so as to give a good chunk of potato to every strong sprout: the end of the potato containing a good many small eyes was cut off and thrown away. Then I planted my potatoes as you would put out cabbage-plants in the furrow, putting ground around them with my own hands. A nice shower came soon afterward, and I pointed triumphantly to my potatoes, 6 inches high with green leaves on them before any of the rest of the potatoes were above ground. June 18th I thought I would see what kind of potatoes there were under the great branching tops. Well, to my astonishment the potatoes were of good size, and a pretty fair quantity in each hill. They brought 35 cts a peck readily. As nearly as I can make out, they were the Early Ohio. Now, then, my friends, do you want any better business than that—in 64 days after planting, a pretty fair crop of potatoes that sell readily at $1.40 a bushel? If I had some more sprouted Early Ohios I



FROM THE HOME OF THE HONEY BEES
MURRAY—HEISS & McLAUGHLIN

OUR MARKET-WAGON AS IT APPEARS BETWEEN 6 AND 7 O'CLOCK IN THE MORNING.

could get another nice crop of potatoes right off from that same ground. The whole thing is a very simple matter, and I mention it chiefly to illustrate the possibilities that are open to those who *claim* to be out of employment.

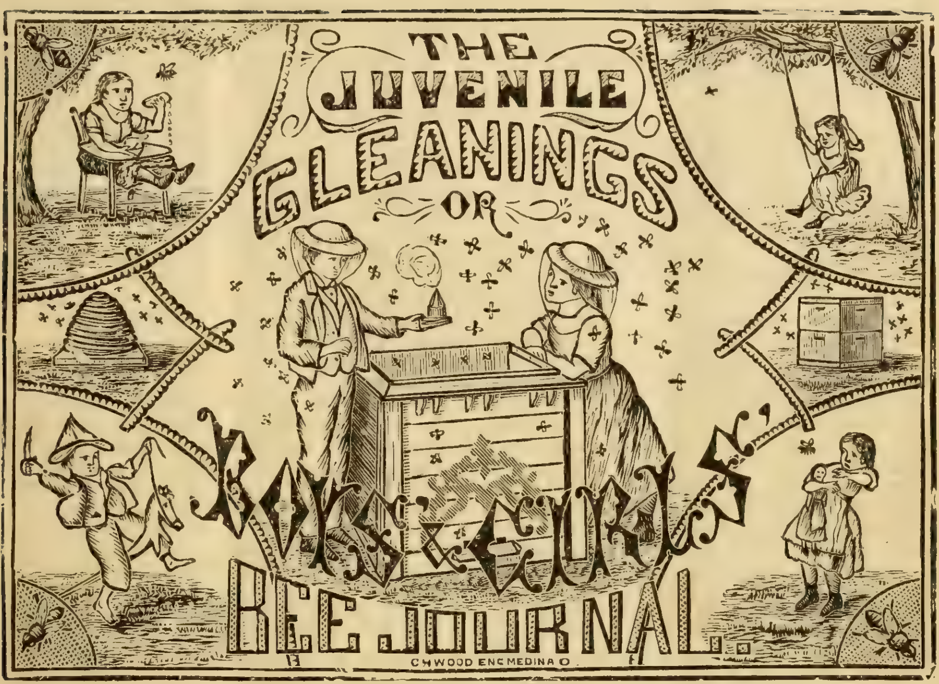
Now, then, once more in regard to the last part of the title of our book, "How to Be Happy," etc. Did I enjoy planting those potatoes? Why, to be sure, I did; principally because I thought I saw a plan of materially shortening the operation of getting early potatoes; and I did it nicely and carefully, so as to be sure they would succeed. They were hoed very little, because the whole crop was finished before the worst weeds got a going; in fact, the care of them was almost nothing. Did I enjoy digging them? To be sure, I did; and I enjoyed it *hugely* too. Some of the happiest hours I ever spent were those employed early in the morning picking out lettuce-heads that were big enough to sell, and, a little later, in selecting those that must be sold at once or their value would be gone.

Let us branch off from plants and animals a little to consider this point of enduring to the end in another way. We all of us complain more or less because things do not move faster, especially in spiritual things. Some years ago I took a boy from our streets, with the hope of making him better. He made me no end of trouble. He used tobacco; and when I discharged him for breaking our rules, he took pains to use blasphemy whenever he saw me, when I had occasion to come near him. By and by he was in straightened circumstances, and wanted work again. I gave him another chance. Again he had to be suspended or discharged. He seemed to be going from bad to worse. By and by he wanted to be tried still again, but it was the old story. I tried hard to be patient—prayed for a quiet and steady spirit, and kept on trying him, even when I had no heart in it, and no hope. Now, my friends, when that boy discovered that I had no spite or revenge, that I was kind, envied not, not puffed up, didn't behave unseemly, and, above all, was not easily provoked, he gradually gave over his bad habits, and, to my astonishment, seemed to, *of his own accord*, respect our rules, and, I am inclined to think, respect *my poor self* in a certain way. I am beginning to admire him, while I thank God for having answered my poor weak half-hearted prayers for him. I had unconsciously been, after a fashion, *enduring to the end;* and without thinking of *saving myself*, the probabilities are now that my quiet course may have saved *the boy*.

Since I have said so much about our market-wagon, I think I will give you a picture of it right here. Our artist has done his work pretty well, only that he has got rather more business about the wagon than occurs as a general thing. The number of men employed will depend, of course, on the size of the town or city; and very likely in starting the business one man would raise all the stuff, drive the horse, and sell out the whole load. Where a good trade is established, the fact that the vegetable-wagon is in the neighborhood may be indicated by ringing a bell or blowing a horn, the way the milk-men do; but where you have got to work up a trade as we have had to, nothing answers like taking a basket of samples and going to the houses. Our boys first tried it by simply inquiring at the door if any vegetables or fruits were wanted; but they soon found that this didn't work so well as to have a basket of samples to show as they went along.

The driver, if he understands his business, will get back in the middle of the wagon when trade commences, and measure up peas, get out what is wanted when the load is large, and make himself busy in a variety of ways. If time is short in loading up the wagon in the morning, the stuff may be put in baskets, and the driver can tie the onions, beets, radishes, etc., in neat little bundles while he waits for his assistant who is going around to the houses. It should be the driver's business, also, to carry a memorandum-book, and take orders, charge up things that are not paid for, and relieve the seller from every thing of this kind. Make it a study to economize time in every way possible; plan to have every thing done on rainy days that can be done under shelter. We do our selling every forenoon. I have often heard Mr. Bushnel say that it was very seldom you could find a salesman who would sell garden-stuff at a good rate all day long. This kind of work draws on one's energies, and therefore the best and most rapid sales are made in the morning. Toward noon the salesman gets tired, mentally and bodily. After he has had a good dinner, and a fair amount of rest, he may be able to do a tip-top afternoon's work in setting out cabbage-plants, cultivating, or something of that sort; at the same time he would have made indifferent work of pushing garden-stuff lively in the *afternoon*. Study your plants; study your helpers; and, above all, study *yourself*.

To be continued Aug. 15.



He that is faithful in that which is least, is faithful also in much.—LUKE 16:10.

MYSELF AND MY NEIGHBORS.

For God so loved the world.—JOHN 3:16.

I WONDER if the little friends to whom I talk have a very clear idea of the many different definitions there are to the word "world;" that is, did you ever think in how many different senses it is used? We often mean by the word "world" the planet on which we live; but that is not the sense in which it is used in our text; for God could not love this planet of itself in the way in which he loves us. The word "world" is used in the Bible many times to indicate the things belonging to this world, which shall soon pass away. We are admonished not to set our affections on worldly things, because they are transient. Well, in our text it is very plain that the meaning is, that God loves the children of men; he loves humanity; he loves the people, all of them, even those who are unlovable; and he loves us so much that he sent his only Son down here to teach us and save us. God loves the people because they are *his* people; therefore *we* ought to love the people. We ought to love the busy throngs of humanity that stream about us and past us in swarms all around the most of us. If we want to be happy in this world we need to love humanity as much as we love ourselves. Loving the people is the opposite of selfishness. When we say that men and women or boys and girls love themselves, we mean that they are selfish. If they love themselves more than all the rest of the world together, they are pretty sure to be very disagreeable. We ought to love them, however, even if they *are* disagreeable. Jesus said, "Love ye your enemies, and do good to them that hate you." You see, if we love our enemies, we shall be pretty sure to love everybody, just as God does. Then we shall be fit to live with God, and to be with him when he sends for us. I believe that, as a rule, children, especially very small children, do love everybody. How the baby laughs and crows, and looks happy every morning! Does the baby at your house giggle and bubble over with fun every day? If the house should burn up, I suppose he would laugh in a very little while, if he didn't while it was burning. He is happy, because it is fun for him to live; and he thanks God for giving him life. Perhaps he does not think of it in that way, but he enjoys every thing —that is, if he is a good baby; and babies, like neighbors, are apt to be very much like their surroundings. Do you reply, that *everybody* loves people—that is, as a general thing? No, everybody does not like his fellow-men. Sometimes we have people who go off by themselves away out in the woods, and purposely get away where there are not any neighbors. We call them hermits. Then there are people who always stay at home. They do not go to picnics or celebrations on the Fourth of July. They don't go to meeting or Sunday-school. They stay upstairs, or out in the fields. Some of them lock the doors so the neighbors can't come in. If they don't lock the doors of the house, they lock the doors of their hearts. They have no friendships or confidants. We call such people misanthropes. "Misanthrope" means a man-hater. Well, now, man-haters are not very common, in one sense; but in another sense they are quite common. The great enemy of mankind, he whom the Bible says goes up and down the world like a roaring lion, seeking whom he may devour, tries to make people man-haters. He persuades them that their neighbors across the way, up street and down street, and all around, are selfish and proud and bigoted and scheming, and bad at heart. Sometimes Satan whispers these wicked thoughts to even the best of us—at least, I believe he does. I think that I, as a rule, love humanity. I like boys and girls, and I like men and women. I like to help them; I like to work for them; and, as a rule, if they do not appreciate my kind efforts, I like them still. I love them because the Savior loved them. If you want to know how much the Savior loved his disciples, read the last chapters of John. He loved poor Peter, even when Peter was so foolish and untruthful and cowardly and weak; he loved poor Judas, even when he knew there was no hope of making a good man of him; he loved James and John when they got so proud and selfish that they wanted to have places in heaven next to himself, and crowd all the rest away. In the chapters I have mentioned, you will notice how earnestly and fervently he prayed for them; and when those wicked men were killing him, he took their part so far as to say, "Father, forgive them, for they know not what they do." Isn't this a beautiful example and lesson for us when we get cross and contrary, and think our neighbors are not lovable?

Well, I don't always feel the way I do now. I wish I did, though. Sometimes I have contrary, ugly streaks, and I feel bad about it, and I am ashamed of it. I don't often let anybody know it, of late years; but sometimes these ugly feelings trouble me for quite a spell. Two or three Sundays ago, while I was in Church, Satan got hold of me. I suspect the first thing that made me cross was because somebody shut down the windows because they thought the breeze was too strong, when it seemed to me that we needed the fresh air very much indeed. I got to thinking how selfish the man or woman was, who sat close to the window. Then I looked at somebody who sat near me, and I felt cross at him. I didn't quite hate him, but I felt cross toward him. Then I felt cross toward the next man, so I thought I would look at some of the nice girls and women, thinking to myself, "Surely, they are lovable;" but, to my surprise, Satan whispered they were proud and silly, and that, in trying to fix themselves up nice, they just made themselves ridiculous. Then I looked at the people, and I began to be frightened to find that I felt hateful toward all of them. Then I looked at the minister. May God forgive me, because, for a brief moment, I felt hateful toward him as well as toward all the rest. I am sure it was not myself, but Satan, who whispered that the preaching was not doing a bit of good—that he was away off from the track, and that there was no use in trying to do any good with *such* a miserable lot, anyhow. I tried to think of something better, and to put away these evil thoughts, but they would not go away. "Lord, help!" began to well up, and finally I prayed most earnestly that God would help me to love my fellow-men. The answer to the prayer did not come right away, but I knew it would before long. I *knew* it would, because I have, hundreds and hundreds of times, prayed in that way before. This time it seemed as if I had got to have a regular rough-and-tumble fight with the adversary. As the wicked thoughts came teeming up, I almost groaned in prayer, "Lord, help me to banish these evil thoughts and evil spirits." Soon after this, peace came, but not much joy or hopefulness. I felt sore (or something like it) over the conflict. But I had done the best I knew how, and I felt a *sort* of happiness, *because* I had done the best I could.

In teaching my class after the sermon was over, I was startled all at once by a feeling that I loved the boys in my class more than I had loved them before for a long while; and the best part of it is, that that bright experience is not gone yet. When I got over to the jail I loved the poor friend I found there, and I plead with him to fight against evil as I had been fighting, for his own sake and for Christ's sake. I came out of the jail a little surprised to find that I was happy—yes, very happy; and the battle I had fought during the day helped to make me happy. It seemed as if it had been a sort of schooling for me—I felt stronger and better for it.

Now, there is almost always a sequel, as it were, to these bad feelings. I told you a month ago of the invisible forces that are at work in these frames of ours. Well, I suspect these forces at times have something to do with this. For some time back I have been getting up very early mornings—at half-past four and five o'clock. By force of habit I got up about the same time that Sabbath morning. Some of you begin to lift your eyes now, and may be think, if you don't say so, "Why, you poor foolish fellow, your overworking yourself was what made you sour and cross." Well, may be it was; but even if so, in answer to my prayer God pointed out to me the mistake I was making, and God helped me to rise above the effects of weariness and fatigue, and to say, "Get thee behind me, Satan." But feeling tired at the time of closing the Sabbath-school and before going to the jail, I laid down on the lounge and slept, I think, *two solid hours*. When I woke up I was in the proper frame of mind to love everybody. Now, look here; don't let's drop this just yet. May be your mother, your wife, your sister, or your child, is overburdened with cares and work, and has lacked sleep. Perhaps the one you are praying for makes slow progress in Christian grace, just because of overwork. What has that to do with you? Why, this much: Don't say a word, but just quietly go and help your mother; find out what she wants done, and do it for her nice and well. Plan to give her the amount of sleep she has been lacking, by bearing part of her burdens. The same with your father, sister, or brother or wife. You can do *this*, even if you are not a Christian; that is, one ought to do this, even if he does not profess to be a Christian. Then branch out a little and try to give a friendly hand to your neighbors in general. Learn to enjoy loving the world, or humanity, and in doing kind acts for them, and by so doing you will have found the pearl of great price.

Let me add, in conclusion, that a nap in the middle of the day, when my nervous force seems to be used up, I have discovered to be worth more to me than any kind of medicine that was ever put into bottles. Some of you may smile, and say, "Oh, yes! it is very well for one to talk about sleeping in the middle of the day, when he can take the time for it." To which I add, I accomplish *more* by so doing. I enjoy getting up with the sun, or a little after; and then when I work myself thoroughly out, I enjoy a good sound sleep between nine and ten. After my nap I can come into the office, right into the midst of the great rush of business, and do lots of *good* work in a very little while, because, you see, I love everybody then; yes, *all the world*, even as God the Father himself "SO LOVED THE WORLD."

MRS. HARRISON'S LETTER TO THE JUVENILES.

SOMETHING ABOUT CARP AND OTHER FISH.

DURING the busiest season of the year in the apiary, I am compelled to be a patient at an institute where electricity and baths are the remedies used. I've been very much interested in the papers in GLEANINGS, "In having something to do, and being happy while doing it." There are ten ponds here that are utilized for the rearing of fish, and I thought that perhaps some of the juveniles might like to know something about them.

There are several springs that issue from the bluffs, and these flow into four ponds. The first reservoir is rather deep, and in it is a school of Rocky-Mountain trout. Two others have fish from the Illinois River; and the fourth, brook trout. In the last-mentioned, cress is raised, as the clear cold water is its native element. I've often wondered whether Mr. Root raised this plant in his ponds, as it has a commercial value in our large cities, equal to lettuce, as a salad.

The other ponds are fed by water from an artesian well, and are used principally for the rearing of carp. The doctor claims that carp grow faster in these mineral waters, as it is warmer in winter.

I watched the old fish spawning one morning; and as they swam in couples around the ponds, throwing the spawn upon the cedar boughs and grass, they appeared to stir up the water like geese or ducks. I examined the eggs through a magnifying glass, and it seemed like a tiny hen's egg, with white and yolk; but the living embryo within was not a chick but a fish. Plenty of tiny carp were swimming around, as no other fish are allowed in the pond, to eat them up. The good dog Major catches the frogs around the border of the pond whenever he gets a chance.

In one pond there are about 1500 yearling carp, and the doctor bated a hook for me to catch some, so I could examine them. I didn't have to wait long before I had a scale carp weighing about a pound, swing around upon the hook. I took out the hook carefully, and, after rubbing its pretty sides, let it glide away into the water, to tell its companions of its adventures. The doctor says, "Now you must try to catch a mirror carp; that one was a scale." The scale seem to bite the best, as I caught a number of them before I caught a mirror; but, oh joy! what a beauty! It had rows that looked like scales as large as nickels, and such pretty colors! I caught one that was leather-colored, and had no scales that I could discover. There were also some fish that they call hybrids. Their father and mother were carp and goldfish. They are very pretty. I infer that carp and goldfish belong to the same family.

It takes work and care to raise fish, as well as bees. The trout are fed chopped beef twice a week; and when they were eating, it made me think of happy boys and girls at play. The carp are fed twice a week, too, on chop—corn and oats ground together.

The iron pipes conveying the water from one pond to another became clogged up, and a pump was screwed on, and water poured in; and by working the handle, soon a stream of muddy water poured out, and in a littte while the water ran out, clear and pure, and the pump was taken off. The fish, in their gambols while spawning, had stirred up the mud in the bottom of the water. Moss grows on top of the water in these ponds, and is taken off occasionally. They had a laugh at my expense, when I asked why they put "wool" in the ponds. When the moss has dried in the sun it looks like coarse white wool, but soon decays. A man with long rubber boots on runs the pipes occasionally, to keep the sulphur or other minerals from clogging up the holes in the pipes. Carp raised in these mineral waters have been eaten, and are of fine flavor. MRS. L. HARRISON.

Peoria, Ill., June, 1886.

THE FLORA OF LOOKOUT MOUNTAIN.

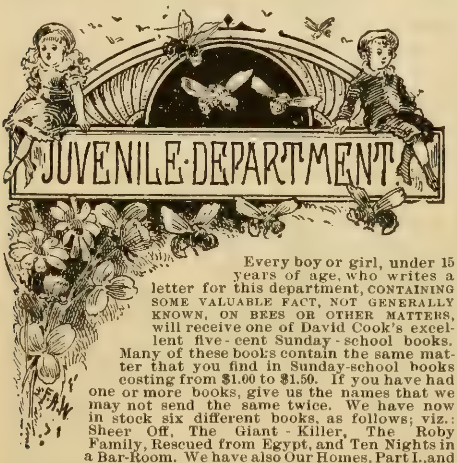
ARE THOSE WHO HAVE APIARIES UPON A MOUNTAIN FAVORABLY SITUATED?

FATHER had 6 stands of Italian bees last fall, and they increased to 11 this spring. The weather has been too wet for them to gather much honey and pollen; and owing to that, we haven't taken much honey from them. The azaleas, laurels, and purple rhododendrons, which grow wild on this mountain, have ceased blooming. The chestnut and sourwood trees are in bloom. The bees seem to be working very well on the red-root, which grows on the mountain-sides. The huckleberries, raspberries, dewberries, blackberries, and June, or service berries, are ripening.

GEORGE LAWSON, age 12.

Lookout Mountain, Hamilton Co., Tenn.

So you are located at Lookout Mountain, celebrated as the place where a battle was fought above the clouds in the late war. As you have represented near you several different elevations, each of which has its own temperature, I should like to ask you if your honey season is not prolonged in consequence of it; that is, doesn't clover begin to bloom first at the foot of the mountain, and, as the season continues to advance, bloom higher on the mountain? You know honey is first secreted from clover south of us, and the honey-flow gradually advances to the north with the season. Now, I have been wondering if there is not the same relation existing between the base of the mountain and the summit. The reason I speak of this is because the matter was mentioned by a writer recently, who has a mountain home, and who said that his honey season was prolonged. Is this the experience of others similarly situated? May we hear from such? ERNEST.



JUVENILE·DEPARTMENT

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from $1.00 to $1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

> "A chiel's amang ye takin' notes;
> An' faith, he'll prent it."

HOW TO AVOID STINGS.

DID you ever hear a bee scold? Perhaps you think he can't, but he can. After he has scolded for a while, talking pretty plainly, too, he will show you that he means what he says by, by—well, by something that hurts; you know what 'tis. If you have never heard a bee scold, just stand a few minutes in front of the entrance of a strong colony during basswood bloom when the bees are pouring into the hive heavily loaded. By and by you will see a little bee (one of the "sentinels," as we call them) twisting his head this way and that, as he surveys the proportions of the huge monster before his little doorstep. Pretty soon he flies up and buzzes back and forth before your eyes—possibly followed by two or three more of his companions, and then he scolds, telling you almost as plainly as I can that, if you don't get out of the way, he will use his little spear. I have heard them scold, and fancy he talks something like this:

"Now, look here, Mr. Elephant, or Man, whatever you call yourself, you are right square in the way. Haven't you got more sense than to stand here hindering us when there are dead loads of honey in the fields? There's not enough honey in the hive to winter on yet, and—just see the bees behind your great carcass, trying to find the door to our hive. If you don't get out of the way I'll stick you in the eye." About this time you will feel nearly cross-eyed, watching the little scamp, while his little voice sounds like a tiny buzz-saw sawing sections.

Now, perhaps the little bee doesn't say just these words; but at any rate he seems to think you have "no business" in front of the entrance, and that he will drive you off if it does cost him his life. So, little folks, I will say that, if you wish to save hard stings, I would advise you not to stand directly in front of the entrance.

Again, our honey season will soon be over in most Northern localities; and when the honey stops off suddenly, the bees will be apt to be cross for a while, especially if you are so careless as to leave bits of new honey lying around, or where bees can get at it by crowding through cracks. Wherever you keep surplus honey, *be sure no bee* can get at it, or you will be likely to have a terrible row, and no end of robbing and stinging. If your bees should get started to robbing during a dearth of honey you may be troubled the rest of the season. The old saying, "Prevention is better than cure," applies to robbing and stings; therefore, little folks, please be careful. When bees get to stinging badly, as they do when robbing has begun, you are liable not only to cause trouble in your apiary, but trouble with your neighbors, which may involve your papa in a lawsuit with them.

The time for you to learn to be careful is now, while you are young. Right habits in the apiary will be easily formed now while you are young, and you will never regret it when you grow older. ERNEST.

NOT GOING TO LET THE BEES SWARM.

I am a little girl ten years old. Ma caught a swarm of runaway bees last fall, and gave it to me. I built it up nicely. They are now trying to swarm, but I pinch off the queen-cells, and won't let them. I call my queen Taddy, and won't let her go again. I love to work with bees, but my big sister squalls every time one comes within one hundred yards of her. **JENNIE H. PARK.**

Concordia, Meade Co., Ky., June 10, 1886.

HOW TO GIVE THE BEES A DRINK.

My papa has kept bees for six years; he takes GLEANINGS. My mamma and sister and I came from Ohio last March. Papa brought his bees here three years ago. The bees out here do not make any surplus honey until after harvest. We have a wind-pump. Papa has a barrel full of water by the pump; he keeps a coffee-sack over it, so the water just comes up to the sack. The bees get on top to drink, and do not get drowned. When papa has queen-cells that he wants to save he cuts them out and puts them under little glass dishes over the other bees, so the cells do not get torn down, and they hatch out all right. **FANNIE GOSSARD**, age 8.

Friend, Salem Co., Neb.

HOW TO STOP ROBBING.

My pa has 20 swarms of bees; he does not get much honey, for he does not run for it. He sells his swarms. This spring he lost a good many swarms by the bees swarming out and trying to enter other hives, and then they get killed and lie on the ground. He has one swarm that makes a business of robbing, and the only way he could stop it was by taking a frame of brood from the others and placing it in the hive they were robbing, and placing the robbers in the place of the hive that was being robbed, and the other in the place of the robbers. He says that will stop the worst robbing. I don't work with bees, though I am not much afraid of them. MAY BELL HORN.

Flicksville, Pa., April 28, 1886.

Thank you, little friend. The way in which your father cures a swarm that persists in robbing is the same as the one given in the A B C book. It works "to a charm," doesn't it? ERNEST.

THE RESULT OF A QUEEN GETTING INTO THE WRONG HIVE.

Pa has five swarms of bees in chaff hives which he made himself. In transferring them into chaff hives the queen from one swarm went into the wrong hive, and we supposed she was stung to death, for we found her dead. Pa takes GLEANINGS, and has your A B C book, and would not be without it. ALMA NEWTON, age 11.

Stella, Vinton Co., O., June 15, 1886.

HOW BROTHER FRED MADE A SOLAR WAX-EXTRACTOR AND FRIED AN EGG WITH IT.

Brother Fred made a solar wax-extractor in the spring, and in March he tried it to see how it would do about melting wax. It does real well. He got some of the nicest wax with it I ever saw. He thought he would try to see if it would roast an egg, so he put one in a dish in the extractor about noon, and about the middle of the afternoon it was cooked — too hard to eat. We were going to have one to eat, but lost it, so we have not tried to roast any since then. Fred had one colony of bees swarm, and took 22 lbs. of honey off, and two 12-pound crates are on yet, and they have got those about half full. PERL Z. CRANSTON, age 14.

Woodstock, Champaign Co., O., June 22, 1886.

Tell your brother that he has done remarkably well. Now, if he or you either will give a clear description of how he made that extractor, so that any one else can make one like it, we will send him any thing he may choose from the 25-cent counter, and possibly we may do better than that even. If Fred's solar extractor will fry eggs, it certainly will melt wax; and I think we all want to know how it was made, as it is probably simple in its construction. Let us hear from you, so it can be published in next Juvenile GLEANINGS. You will remember that I fried an egg, but, like your egg, it was cooked so hard as to be unfit to eat. ERNEST.

MORE ABOUT BROTHER FRED'S BEES.

We have a little cherry-tree in our yard, that father was mowing around one day, and we noticed on the tree, right down close to the ground, that the bark was bursted, and quite a number of little roots were coming through. The bark was bursted in three places. It looks odd. We have about 80 little chicks and 23 goslings. Brother Fred's bees have swarmed four times. The first swarm that came out, Fred and Perl had just started out to work after dinner, and we rang the bell for them, and before they could get here the bees started off, and father stopped them by throwing cupsful of water on them while they were flying. I like to help hive the bees. Fred has ten swarms now, and they are all doing well, and we are expecting more any time. NETTIE H. CRANSTON, age 11.

Woodstock, Champaign Co., O., June 22, 1886.

You are sure, are you, that the water had the effect of bringing the bees down? ERNEST.

FROM TWO NUCLEI TO 12 COLONIES.

Pa made a new start last year with bees, by getting two 3-frame nucleus colonies of Italians from Hemphill & Goodman, of Elsberry, Mo. These nuclei increased to 12. Pa sold one swarm, and we let two get away. We had 9 to start in the winter. All wintered well on their summer stands. We have sold 3 swarms, and have hived 7 and lost several. Pa has some of the queens' wings clipped. We have some beautiful queens. I like to look at them. We have taken in all about 150 lbs. of honey this spring, and pa says he could take about 200 lbs. more right away if he had the time to do so. He makes his hives and frames himself. We use altogether the Simplicity pattern of hive, for pa thinks it is the best. We all like to read GLEANINGS. Pa says it has much of a Christian spirit about it that is good, and says that he is strongly in favor of uniting religious matters with bee-matters. We all esteem your Christian spirit highly. My letter has become quite long already. I wish to say before I close that I have one sister and three little brothers here, and two brothers gone to live with Jesus. I am the eldest living, ten years; my eldest brother living is named Ernest—a namesake of Mr. Ernest Root. ESSIE STAFF.

Moscow Mills, Mo., June 26, 1886.

BEES FLYING INTO THE NOZZLE OF THE SMOKER; HORNED TOADS.

When my father is at work among the bees, he sometimes smokes them away, and they have so much curiosity as to fly right into the nozzle of the smoker, and there are burned. My father has about 150 stands of bees. I have for pets, horned toads. They are rather hard to catch; and when I do catch them I bring them home and put them in a tin pail or bucket, and keep them a few days and then let them go. They can live a long time without any thing to eat. EDDIE BUTLER, age 12.

Los Gatos, Cal., June 19, 1886.

It it quite a common occurrence for bees, when enraged, to fly into the nozzle of the smoker. This is somewhat the way little boys and girls do when they are mad—they rush right into something that is sure to bring them to grief, without thinking or knowing the consequences. — Don't you think you are just a little cruel to keep the horned toads several days in a pail without any thing to eat. This I judge you do, as you say they will live a long time without food. We have one now in our apiary, which has been sent us by one of our friends. I presume it was in the mails nearly a week; but when it arrived it was very evident that it was quite *weak*. ERNEST.

WHY DID OUR BEES LEAVE?

Papa bought a stand of bees last spring, and from that he had five stands. He thought he could winter the fifth one; but the poor bees died, so he had four good stands this spring. On the 11th of April, two left, and their hives were full of honey. They went to our nearest neighbor's, and his bees killed all of ours, and on the 21st of April the third stand left. Please tell me why they left. Papa was sorry. He likes to work with bees and honey. The hives were all clean and nice when they left.

Frances Hemmerly.

Forest, Hardin Co., Ohio, June, 1886.

I can not tell why your bees left, friend Frances. It is a matter that has been much discussed. Sometimes they seem to get discouraged and swarm out because they are few in numbers. It seems to be a sort of mania some certain seasons. A few years ago we used to have a good deal of complaint of swarming out in early spring; but of late we have seen but very little of it. I think strong colonies are the best preventive.

HOW TO MAKE HONEY CANDY.

My pa takes Gleanings, and I like to read the juvenile letters. Pa has 50 colonies of bees, and he clips his queens' wings, and thinks he can hive bees a great deal better that way than any other way. I will tell you how we make honey taffy to make it look like store candy. We boil our honey until it is stiff enough to pull, then we pour it into greased pans and let it cool; then we take it out, dividing it, leaving part red, and take the other part and pull it till it is as white as we can get it; then we draw both the white and red out to the size of a stick of store candy, then twist them together, making striped candy; then lay it on a plate. Ma uses honey for almost every disease.

Forest City, Mo. Lizzie E. Purvis, age 13.

Thank you, friend Lizzie, for your simple recipe for making honey candy. I have no doubt but that it will make a very wholesome and nice confectionery—much better, indeed, than the cheap candies we buy. I think I shall have to get that queen clerk (I mean my other half) to make some, and I will then report how we like it. By the way, is it not a good idea to devise as many new uses for honey as we can? Our friend Muth, of Cincinnati, is getting honey introduced for mechanical purposes. Our friends Crawford & Taylor, the bakers, mentioned in another column, have succeeded in making what I call extra nice honey-jumbles. Our friend Arthur Todd, of Philadelphia, makes and advertises honey candies. You see, all these different uses for honey help to raise the price of it. Shall we not have more reports (get your mamma to help you) on how to make honey candies, honey-cakes, etc.?

Ernest.

SHALL WE KILL SWARMS TOO WEAK TO WINTER?

Two years ago we started with one swarm of bees. There were no swarms the first year. Last year we increased three and killed one that was not strong enough to go through the winter, and now we have 11. Two got away; all were by natural swarming.

Tilden, Ill., June 9, 1886. S. J. & Wm. M. Boyd.

Thank you, friends S. J. & W. M.; but why should you kill a swarm because it was too weak to winter? Why did you not do the best you could with it, and run your chances of its living through the winter? You see, you would have been so much ahead if it had survived.

NOTES AND QUERIES.

A KIND WORD FOR MRS. COTTON.

I HAVE received several letters from bee-keepers asking me if Mrs. Cotton ever sent me the colony of bees that she promised to send me this spring. She did. About the first of May I received from Mrs. Cotton a swarm of nice Italian bees in shipping-box, and I don't think they are inferior to Prof. Cook's celebrated strain, which is saying a great deal, for I have some that came from his apiary. I will tell what else was in that box. There was as fine a queen as I ever saw. I put them into the Controllable hive that Mrs. C. sent me last year. They have given me two large swarms, and are working in the sections, and gathered more honey than any other colony that I have; so, score one for Lizzie.

Hiram Adams.

Port Austin, Mich., June 28, 1886.

[We are very glad to get the above report, friend A. With the very large prices Mrs. Cotton charges for whatever she advertises, she certainly ought to give *good measure* and *good quality*, and we are very glad if she is beginning to do so.]

CONDITION POWDERS, EGG FOODS, CATTLE FOODS, ETC.

[It seems the Philadelphia *Farm Journal* looks at these things a good deal as I do. We clip the following from a recent number:]

We have no faith in condition powders, condimental foods, egg foods, and the like. They are all in the same boat with patent medicines. A poultry powder that sells for 50 cents a box was found by Prof. Jordan, of Maine, to contain 84 per cent of mineral matter, chiefly ground shells and a little bone, the rest being water and organic matter. A celebrated cattle food was found to be composed chiefly of wheat bran and corn meal, with a trifle of fenugreek, and a little sulphur. This was sold at 8 cents a pound.

DOES THE DRUMMING ON TIN PANS BRING DOWN SWARMS?

In the June 15th No. I see an article from J. J. H., in reply to which you say you would like to know if drumming on tin pans, or any noise that is produced to arrest a swarm of bees, does any good. I can tell you that any noise that may be made when a swarm issues, to drown the noise of the leaders of that swarm, will settle them on the nearest branch that is accessible. I have come to this conclusion from four years of experience in the bee-business. When I was there with my tin pans I always saved a swarm; when not, they were lost.

Samuel D. Bates.

Sikeston, Scott Co., Mo., June 15, 1886.

MRS. CULP TELLS US SOMETHING ABOUT HER NEW PUPIL.

Please accept thanks for the neat little compliment paid me by yourself and our brother "Just Hatched." Permit me to introduce him to you and the bee keeping brethren and sisters generally as our minister, the Rev. J. S. Rickets, of the Ohio Conference, hoping you will all extend to him the right hand of fellowship—I'm quite sure you will all feel quite proud of him when you form his acquaintance; for he is, in my estimation, a very precocious bee-keeper. Just think of his writing for the bee-journals before he is a month old! With his and wife's assistance occasionally, things are moving on grandly in the apiary.

Hilliard, O., July 1, 1886. Jennie Culp.

BE CAREFUL HOW YOU DRIVE HORSES NEAR TO BEE-HIVES.

[The following comes as an additional warning to what has already been said:]

On the morning of the 9th inst. I lost a valuable family, saddle, and harness horse—stung to death by bees, caused by the neglect and disobedience of a hired man. He drove the horse with a loaded cart into an apiary of forty hives, but he did not turn as instructed. An effort was made to move the horse, but it could not be done until he had upset two hives, moved others and turned the cart over. The horse was removed by my wife and neighbors, and every effort was made to counteract the poison, but in vain. He died in two hours, of fits. J. A. SMITH.

Elora, Lincoln Co., Tenn.

JUST COMMENCED TAKING OFF HONEY.

I thought I was too poor to take GLEANINGS any more, but I find I can not do without it. I commenced the campaign with 52 swarms of bees. I have just begun taking off honey, and have taken off, up to date, about 300 lbs. The most of our honey is raspberry. SIMMONS WARFLE.

Tracy Creek, Broome Co., N. Y., June 11, 1886.

A B C OF POTATO CULTURE TO BE PUBLISHED IN THE SWEDISH LANGUAGE.

Mr. Stalhammar, editor of the *Swedish Bee Journal*, Gothenberg, Sweden, writes for a copy of "Winter Care of Horses and Cattle" *as soon as it is out*. He is intending to publish "A B C of Potato Culture" in Swedish. T. B. TERRY.

Hudson, O., May 5, 1886.

PERFORATED ZINC.

The sample of perforated metal is received. The perforations are too large for my purpose. I have several of Alley's queen-traps which have the same sized perforations as the sample sent. The principal purpose which I make of the traps is to capture the queens of second and third swarms; but I find that, while they will catch all old or laying queens, they will not do so with all young ones, many getting out and going with the swarm, but I think they could not do so with the smaller size of perforations.

East Key, N. Y. O. M. WHITCOMB.

[Are you sure young queens can get through the perforated zinc we sent? We selected some of the smallest queens in our apiary, but we could get none through it; see page 424.]

Tobacco Column.

HAVING noticed in GLEANINGS that you are offering one of your bee-smokers to every one who will agree to quit using tobacco, and not knowing whether I am entitled to one, I thought I would state my case to you, and see if you think I ought to have one. I had used tobacco for 6 years, and had tried to quit once before, but failed; but I am glad to say that at present it has been 16 months since I took a chew of the weed, and I feel safe in promising to pay you well for the smoker if I ever use the weed in any form again. If you think me worthy of a smoker, I shall take it as a favor. W. L. BANTA.

Valley Spring, Tex., April 28, 1886.

Friend B., our offer of a smoker is to those who give up tobacco because of what has been said in GLEANINGS in regard to it; but as you give us the usual promise, we have sent you a smoker to kind o' clinch the bargain. Now, you see if you ever put another bit of tobacco in your mouth it will cost you just 70 cents.

I received the smoker you sent me. I was very much pleased with it, and am much obliged. If I ever commence the use of tobacco again I will send you your dollar. C. H. MARTIN.

Lee, Allegan Co., Mich., June 4, 1886.

I certify on honor that I have abandoned the use of tobacco, and desire your promised boon. I also certify on honor that I will pay for the smoker if I ever commence the habit again. W. W. WOOD.

Wallaceburg, Hempstead Co., Ark., May 21, 1886.

ONE WHO IS 24 YEARS OF AGE QUITS, AFTER HAVING USED TOBACCO FOR EIGHT YEARS.

After using tobacco for eight years I have quit, and expect never to use it again, although I am only 24 years old. If you think I deserve a smoker, please send me one; and if I take up the habit again I will pay for the same. JOHN W. WRIGHT.

Cass City, Tuscola Co., Mich., May 1, 1886.

My friend E. C. Kitchens tells me that there is due me a bee-smoker, as I on the last day of last December quit using tobacco, with the intention of never chewing or smoking any more. I have been chewing tobacco nearly all my life. I am 47 years old, and a native-born Texan. I make the usual promise to pay for the smoker, if I break the pledge. J. A. ISAACKS.

Brownwood, Tex., April 9, 1886.

THE GOOD EFFECT THE TOBACCO COLUMN IS HAVING UPON OUR READERS.

I have seen that so many have quit the use of tobacco who read GLEANINGS, that I have also given it up after using it over 20 years. I am determined to quit for good by the help of the Lord. If you think me worthy of a smoker you can send me one; and if I ever use tobacco again I will pay you for it. GEO. W. BECKHAM.

Pleasant Hill, Lanc. Co., S. C., May 10, 1886.

A THIRTEEN-YEAR-OLD BOY WHO HAS USED TOBACCO FOR FOUR YEARS, HAS NOW QUIT.

I see in GLEANINGS that you give a smoker to everybody who quits the use of tobacco. I have one hive of bees, and am 13 years old. I have smoked and chewed for 4 years, and have quit. Please send me a good smoker; and if I ever use tobacco again I will send you the price of the smoker twice; but I hope I shall never use it again. STACY NAYLOR.

Beloit, Mahoning Co., O., May 12, 1886.

BY THE HELP OF GOD, WILL CONQUER THE HABIT OF USING TOBACCO.

I like your A B C book and periodical well. Please don't send me a smoker, for it would bring up unpleasant recollections of repented and forgiven sin; yet accept my thanks for your kind interest in me and my fellows in tobacco guilt. I have reformed entirely, and have induced Rev. S. T. Williams, of Philadelphia, N. Y., to quit. He burned his tobacco and pipe, and dropped on his knees with me, for help from on high to enable him to conquer the world, the flesh, the devil, and the *weed*. The bee-men of this locality are scarce. T. HOWLAND.

Clayton, Jefferson Co., N. Y., May 8, 1886.

My pa began to read GLEANINGS last fall, and on Christmas day he quit the use of tobacco. I have one stand of bees. If you will send me a smoker I will send you the price of it if my papa begins to use tobacco again. He says he will never use it any more. GILMER R. HOUCHINS.

Pipestem, Summers Co., W. Va., May 17, 1886.

HERE IS THE RESULT.

I received my smoker, and my pa received his "Dose of Truth." He thinks it a grand document. His weight last Christmas was 175 pounds. Since he has quit the use of tobacco he has gone up to 207 pounds. His friends say he will have to commence it again, but he says, "No, *never*."

GILMER R. HOUCHINS.

Pipestem, W. Va., June 7, 1886.

That is the kind of talk, friend Gilmer. Tell your father not to take up tobacco again, even if he should weigh half a ton.

TWO MORE WHO TAKE THE PLEDGE.

Giving up tobacco has become so much of an established fact that a couple of men recently came into our store, asking for smokers, saying they were going to give up tobacco, and were willing to have their names published; and if they ever use it again, they will pay for the smokers. The names and address are as follows: Alex. McKee and U. B. McIntyre, Hinckley, O.

KIND WORDS FROM OUR CUSTOMERS.

I have received the labels, and am very well pleased with them, both as to quality and price. Thanks.
Anaheim, Cal. ALFRED W. HINDE.

I have received the goods I ordered of you. They gave perfect satisfaction. The sections were the finest I ever saw. W. A. ANTHONY.
Sasser, Terrell Co., Ga.

My foundation came to hand June 19th. It was the best I ever had. Please accept thanks for your kind and prompt attention. MRS. M. A. WILKINS.
Seneca, Nemaha Co., Kan., June 22, 1886.

I received sections and other things in good order. I am very much pleased with them. I will order some more soon. HENRY WALTER.
Orange, Orange Co., Tex., June 22, 1886.

I received the $1.00 queen from you some time since. I introduced her in a hive of black bees; when her eggs hatched I found they were very bright pure Italians. I am very much pleased with her. C. MOORHOUSE.
Hibernia, Fla.

Wife says we enjoy the Home Papers very much, and wishes you may be spared to give them to us for many years yet. You see I have put it *we*, because I agree with her, and feel that GLEANINGS would lose a great charm, and that its power for good would be lessened very much by the omission.
McMinnville, Ore. FRANK S. HARDING.

PROMPTNESS.

The imported queen came to hand June 2d. I introduced her at half-past 6 P. M., on the same day. To-day, June 3d, at 3 P. M., she has laid over 200 eggs. How is that for introducing imported queens? Thanks for promptness. I did not think you would receive my order in that short time.
La Salle, Ill. THOMAS GEDYE.

OUR CAREFUL PACKING.

The goods came in good condition, and were quite satisfactory. When I deal with you, friend R., I am never fearful that, when my goods come, they will be carelessly put up, and consequently damaged on arrival; and when I see them I feel like exclaiming, "Oh! if everybody would be as careful, how much pleasure and benefit it would amount to in the world." JOHN S. WOMBLE.
Oviedo, Orange Co., Fla., June 24, 1886.

I received goods shipped by you. The order was correctly filled; goods came in fine order. I am well pleased with every article and style of packing—so much so that I expect to give you my entire patronage in the future. W. F. COOPER.
Itasca, Hill Co., Texas, June 6, 1886.

WELL PLEASED WITH OUR BEES.

I received the bees June 12th all right. I am much pleased with them. Many thanks for the extra frame and the amount of bees you sent. Your mode of shipping is all right. I am well pleased with the A B C book. I hope I may have success. To-day, June 18, they are working finely.
Woolwich, Pa., June 18, 1886. F. T. RAHORN.

PERFECT SATISFACTION.

Your goods on both shipments came all right, and were of good quality. I could get them nearer; but I am so well pleased with my deal with you that I do not see the place to break off, and the goods give perfect satisfaction. JOSEPH SWIFT.
State Center, Ia., June 11, 1886.

OUR TEN-CENT HONEY-KNIFE.

It may not be amiss to tell you that your little ten-cent honey-knife, which cost fifteen cents by mail (and none of my friends guessed a less price than 25 cents) proves itself a great convenience. It is little, if at all, inferior to the longer and more expensive patterns. DAVID STRANG.
Lincoln, Tenn., June 22, 1886.

I think the California honey "takes the cake"—perfectly magnificent, but a great many don't like it. J. M. JENKINS.
Wetumka, Elmore Co., Ala., June 17, 1886.

[Friend J., it is a little singular that we have so many reports just about like yours. A good many people think that California honey is "magnificent," as you say; but, strange to add, others don't like it; and, as you say, those who "don't like it" are "a great many."]

G. M. DOOLITTLE'S OPINION OF TERRY'S NEW BOOK.

Terry's "Winter Care of Horses and Cattle" is at hand. It is a book that should be in the hands of every person in the land. With many, the height of their ambition seems to be the largest numbers with the least attention; in others, a poor old horse — so poor you can count every rib 50 feet away, to push and spur through every day.
Borodino, N. Y. G. M. DOOLITTLE.

GLEANINGS AS AN ADVERTISING MEDIUM.

I ordered a select tested queen of you, May 24. In eight days she was here, and in the hive. On the ninth day she was laying. That is business on time, I think, from North Carolina to Ohio. I am well pleased with the Buckeye window-sash lock. How was the candy made that was with the queen—all sugar, or not? When made of honey and sugar, do you dissolve the sugar in water, and how long does it take to cook it? I got into business by inserting an advertisement for black queens, in GLEANINGS. Orders came from all over the Northern States till I had to say stop. I am Italianizing all that are in reach of me; and as fast as I can find hybrid queens, the friends can have them.

W. P. DAVIS.

Goodman, Anson Co., N. C., June 12, 1886.

[The bee-candy is simply honey and powdered sugar made into a stiff dough. See A B C.]

TERRY'S NEW BOOK.

[The kind notices of this little volume are at hand by the hundred. We select the following from among them:]

"The Winter Care of Horses and Cattle," is the title of a pamphlet from the pen of T. B. Terry, "so well known as an able writer in the agricultural papers, as well as a 'live man' at our agricultural Institutes." This very humane and Christian work should be in the hands of every one who owns or drives a horse or provides for the wants of domestic cattle. The reading of the book will undoubtedly increase the number of merciful men and women, and assist largely in promoting righteousness in the earth. Every thing connected with the prosperous management of these animals,—the shelter, feeding, watering, etc., etc., is illustrated in the most careful manner.—*The Manifesto, Shaker Village, N. H.*

OUR HOMES.

What doth the Lord require of thee, but to do justly, and to love mercy, and to walk humbly with thy God?—MICAH 6: 8.

HAVE you ever wondered, dear friends, why it was necessary to have so much discussion in regard to the way a Christian ought to live? If all these things are really important, it would seem that one almost needs to have a theological education in order to be able to live a Christian life. Yet we know this is not so; for Jesus accepted and pardoned the lowliest and the humblest, and many of the most illiterate. Do we not sometimes make a mistake in encouraging the idea that it is a very hard thing, or a very difficult thing, to understand just how we should behave and act, to be followers of Christ? Is it not possible that we are troubling or worrying ourselves over things that are, after all, of no very great importance? In the verse just before the one containing our text the prophet asks, "Will the Lord be pleased with thousands of rams, or with ten thousand rivers of oil?" The answer is given in our text. The words before the text are these: "He hath showed thee, O man, what is good;" and then follow these simple little directions — "Do justly, love mercy, and walk humbly before God." Surely the veriest child among us knows how to do this; but suppose, for instance, he does not. Suppose the one who wants to be a Christian is so young or so ignorant, or that his former educational surroundings have been so faulty, that he has false ideas of justice—what then? Well, my opinion is that the *will* will be accepted in that great day for the deed. I am sure that no honest, penitent child will ever be cast out when he was doing the best he knew how. Perhaps no one will dispute this. If so, then the question comes up to all of us, Are *we* doing the best we know how? Did you ever think of the readiness with which the world in general answers this question? The inmates of our prisons almost invariably say, when you sit down beside them, and have a frank, friendly talk, that they have been doing the best they knew how. If they told the honest truth, it seems to me they ought to say, "I meant to do right, but I allowed myself to be prejudiced;" or, "My mind was so much taken up with something else that I did not give the matter the attention that I ought to have done." If he has the real genuine spirit of Christ in him, I should like to hear him add, "I have done wrong; and if you will tell me how I can right the wrong, I am ready to do it."

In our recent Sabbath-school lesson I have been greatly interested, or, rather, I have made it a point of study, to see if there is any chance for those who refused to accept Jesus, to make the plea that they were "honest doubters." When he opened the eyes of him that was blind from birth, the Pharisees were displeased. Instead of rejoicing that a prophet, or even a physician, was among them, with power to perform such cures as this, they objected and found fault. First, they refused to believe that he was the man who sat and begged; and when he himself declared, "I am he," they were not satisfied. They sent for the parents and questioned them about it. But even the poor parents were so blinded and bigoted, or cowardly (I can not make out which), they were backward, and evaded the question by saying the young man was of age, and that he could answer for himself. Finally they began to find fault, and to say that this prophet was not of God, because he healed the man on the Sabbath day. The observance of the Sabbath day, according to their formula, was a matter of so much greater importance than giving sight to the blind that they ignored the miracle, and said, "This man is not of God, because he keepeth not the Sabbath day." Does it seem possible that men could become so bigoted and contrary as to use such reasoning as this? Long before this they complained that he did not observe the Sabbath day according to their code; but he answered them, "The Sabbath was made for man, and not man for the Sabbath." At that same time he healed the man with the withered hand; and we are told they were watching him, ready to take it up against him in case he should perform a miracle on the Sabbath day. He silenced them, however, by propounding a question which their own consciences would not permit them to answer untruthfully — "Is it not lawful to do good on the Sabbath days?" Geike, in his Life of Christ, tells us they had a law forbidding work on the Sabbath, unless it was to save life. According to such a code, suppose that a man had a toothache on Sunday, he must grin and bear it, for it would be breaking the Sabbath to go for a doctor or a dentist. And while we are on this matter of the Sabbath, are we not some of us in this nineteenth century in danger of making an idol of the Sabbath day, and bowing down to it as did the heathen in olden time to their senseless idols?

The question is before our nation just now —What shall we do on Sunday? I believe pretty nearly all agree that it should be a day of rest for man and beast. Many would go still further and add the word "recreation," making it a day of rest and recreation. If farmers who live in the country go to church on Sunday, they must use their horses; and there are some who say that, after their horses have worked hard during the week in plowing, or in haying and harvesting, they, too, ought to rest on the Sabbath. I am afraid that just a little of the leaven of the Pharisees is getting in here. Usually there are horses enough on the farm to take all the family to church, without being very heavily burdened; that is, where churches are at a moderate distance from our homes, as they always should be. If the horses are properly cared for during church time—put in comfortable sheds, for instance — I do not see why they can not rest as well as if left standing all day in the stables at home. In connection with this event Christ gave us a little text that has always been a comforting one to me. He said, "Wherefore it is lawful to do well on the Sabbath days." He said this in connection with the question about a sheep, if it should fall into a pit on the Sabbath day. The first commandment is against idolatry. Did it ever occur to you, dear reader, that we may be in danger of worshiping the Sabbath in a senseless way? Jesus never laid down a law without sense. In heathen lands, where they are in the darkness of superstition, they have their "taboos;" that is, laws are laid down in a senseless way. Physicians used to doctor people by giving them the liver of a frog or a piece of a serpent's skin; a cold in the head was cured by kissing a mule's nose. Frogs boiled in vinegar cured the toothache. While enumerating these, I have wondered if there were not some tincture of this taboo of heathenism still lingering among us.

Now, there is nothing about religion and nothing in Christ's commands, that is, in any shape or manner, the slightest akin to such superstition. God surely never intended to lay stress on something that had not reason and sense back of it. God must be just, or he would not be God. Earthly rulers may put burdensome commands upon us, and may punish us for breaking such laws; but God the Father never did. Is it possible that a kind and just parent should ever lay down laws for his children, simply for the sake of punishing them when they break his laws? Surely not.

A few days ago we were led to believe that the Postoffice Department of the United States had purposely made a ruling that queen-bees might pass through the mails, and that the ruling was to be literally carried out. A queen could go, and nothing but a queen; not even a single worker to go along as company and to feed her. I said at once that I did not believe it possible that the men whom we have occupying high offices could for a moment intend any such ruling. If they did it would be something like this: Suppose our great men at Washington should meet together in making laws for Uncle Sam's subjects, and should discourse in this way: "Oh, yes! there is that miserable lot of bee-men who are petitioning for the privilege of sending queen-bees through the mails. Now we will just play a trick on them. We will make a ruling, permitting queen-bees only to pass through the mails, and then we will instruct the postmasters, through the Postal Guide, to refuse every cage that has a worker-bee in it. We will tell them to throw them out or hold them until they starve to death. We will destroy so much of their property in this way that they will never want to come to Washington again." Now, suppose they laughed and jeered, and had a big time of it, to think of the wail we would send up at the loss of our property. Are we under such rule as that? Why, to be sure, we are not. The idea is ridiculous. Ancient kings may have had the power, and possibly the inclination, to grind down and harrass their subjects in this kind of a way. But *we* are a Christian nation; a just God rules over us; and the thought that God could lay down laws for us, his children, in any such way, is to me the worst kind of blasphemy. You will notice on page 537 some remarks in regard to this matter. To show you that my faith in this government and its postoffice officials was not misplaced, I take pleasure in submitting the following:

> POST OFFICE DEPARTMENT,
> *Office of the Gen'l Supt. of R'y Mail Service,*
> WASHINGTON, D. C., June 29, 1886.
>
> *A. J. Cook, Esq., Agricultural College, Mich.*
>
> SIR:—Yours of June 24th, regarding a modification of the postal regulations admitting queen-bees to the mails, has been received, and I am happy to inform you that this regulation will be so modified in the next monthly Postal Guide as to read, "Queen-bees with necessary attendants."
>
> The question as to the dispatch of queen-bees to Canada has been referred to the Superintendent of Foreign Mails. Very respectfully,
>
> JNO. JAMESON, *Genl. Supt.*

You will notice that it was a prompt reply to Prof. Cook's inquiry.

Here is another, sent to the Hon. Edwin Willits, President of the Agricultural College, Michigan, which is interesting to us, inasmuch as it also touches on the matter of sending queens to Canada. It was sent to me by the kindness of Prof. Cook:

> POST OFFICE DEPARTMENT,
> *Office of the Gen'l Supt. of R'y Mail Service,*
> WASHINGTON, D. C., June 28, 1886.
>
> *Hon. Edwin Willits, Agricultural College, Mich.*
>
> SIR:—I have the honor to acknowledge receipt of yours of June 23d, regarding the admission of queen-bees to the mails *with attendants*, and I am pleased to be able to inform you that the regulation will be modified in the next monthly Postal Guide so as to read, "Queen-bees with necessary attendants."
>
> In regard to forwarding queen-bees to Canada, this office, of course, has nothing to do. I see no objection to the postmaster at the mailing office receiving them for such dispatch; and if the Canadian authorities see fit to receive them, this office certainly has no objection. This question has been referred to the Superintendent of Foreign Mails.
>
> Very respectfully,
>
> JNO. JAMESON, *Genl. Supt.*

May God grant that peaceful and Christianlike relations may exist between Canada and the United States in the interchange of queen-bees, as well as in every thing else!

Now, friends, do you not see what a sad thing it is to lose faith in our own government? and this includes faith in those who occupy high official positions. And is it not, too, a thousand times sadder to lose faith, or to lack confidence in God, the great Father of us all? When we allow ourselves to believe for a moment that he has laid down laws for us that are not easily understood or comprehended, and that terrible judgments shall follow the consequences of even ignorant trangressions, do we not belittle ourselves, and forget the opening words of the prayer the Savior gave us—our Father who art in heaven? What is it, then, the Father wants of us? Why, simply what is expressed so plainly in our little text—do justly, love mercy, walk humbly before God. Very little question need arise in regard as to what is doing justly. Where a man is not straight and honest in deal, even a child, or one of no education, will detect it. How often we hear the words, "Is that fair or Christianlike?" and when the circumstances are submitted, there is usually but very little difficulty in getting a unanimous reply. If it is a question that involves complications, settle it by arbitration. Let each party tell his story, and then let some good man or woman decide whether it is fair or Christianlike.

Now, in regard to the second command laid down in our text—love mercy. Is there any difficulty in understanding what the prophet means by this? Of late I have been linking this word mercy with Christ's words I have spoken about it, bidding us to do good on the Sabbath; also, "A merciful man is merciful to his beast." I like to go around on Sunday morning, and see that the chickens have every thing pleasant and comfortable. I love to caress the mothers that have lots of chickens. One of my Brahmas finally hatched 13 out of 14. She is only half Brahma, and so she is not so clumsy and awkward. She used to be very shy, but now we are excellent friends. I love to make friends with the horses Sunday morning too. Then I love to fill the big stone watering-trough in front of the factory, so all the horses that pass by during the day may have a drink. Yes, I love to see the bees sipping the water down by the brook.

A few days ago a man with a big team passed by our watering-trough. The horses quickened up at the sight of the water, and by the motion of their lips showed how thirsty they were. But he yelled at them to go on, and hit them with the whip. Their ears dropped back, and they looked disappointed and weary. The thought occurred to me of trying to make him stop and water those horses; and it was not until after he had got quite a distance past that I remembered that I was President of the Society for the Prevention of Cruelty to Animals, for the town of Medina. I am afraid I am a rather poor president. Of course, it is of more importance to look out for suffering humanity, rather than for the suffering domestic animals; but in our locality humanity seems to be so well cared for, especially as far as food and drink and clothing are concerned, that I have not thought so much about it.

Now we come to the last clause of our text. What is it to walk humbly before God? Well, I think almost any child might answer this question. The friend in jail told me recently that he had nothing to thank God for in the way of giving him an existence. He said he had never felt it to be a favor, and that God could take away his existence as soon as he chose—the sooner the better. This surely is not walking humbly before God. Walking humbly before God is, as I understand it, letting God rule—thy will, not mine be done. You may say, if you choose, "I can not just see why God put me here in this world to endure pain, affliction, and sorrow; but as I am here, and by his order, I am going to say, 'Praised be his holy name.' I am going to obey him so far as I know how, and I am going to make the best use I can of the powers he has given me. I am going to strive to honor and glorify him in all that I am and all that I do. I am going to let thoughts of him come first and foremost, and in place of every thing else. I am going to strive against selfishness and pride; against stubbornness and ill temper. I am going to be his child, and he is to be now and evermore my Father."

When I was studying the subject of becoming a Christian, years ago, I went to the pastor of the church where we usually attended. I had got it into my head that, to become a Christian, I should have to debar myself from many things, and must become cramped, or under bondage, as it were, to fixed rules and laws. To my surprise, he stated that most of the things I mentioned were more matter of opinion than any thing laid down by church creed or by the Bible; and in reply to my questions he stated the few essential things needed.

"Why, Mr. Reed, is it really true that this is all that is required?"

"It is all, as I understand it, Mr. Root."

I can not remember now, but I think the conditions he mentioned were pretty much the same as our text to-day—do justly, love mercy, walk humbly with God. As I started to go home, after having knelt with him in prayer, and promised before God to do the best I knew how to follow Christ, it seemed as if the greatest freedom and liberty that I had ever known before was spread out before me. All the barriers were removed from every thing that I wanted to do; for I was, once in my life, free from the bondage of sin, and walking in the broad sunshine of God's great love to his children.

OUR OWN APIARY.

REVERSIBLE FRAMES; ROBBING, AND HOW TO PREVENT, ETC.

OUR reversible wire Simplicity frames are still giving us excellent satisfaction; and the more the boys use them the better they like them. As I now see the advantages to be derived from their use, I wish all our frames were reversible. I do dislike to see combs built within a half-inch or so from the bottom-bar, or holes eaten around the lower end of the brace-wires. Such combs not only look badly, but are more liable to make the top-bar sag, unless a folded tin bar is used for a brace. They give us less space for brood and honey, and are more liable to break down during shipment than where combs are built out solid, as is accomplished by reversing. We now have secured some beautiful solid sheets of combs by it. Said combs look as if they might stand shipment without a single wire, though I hardly think it would be policy to ship them thus. However, it does seem to me that when combs are reversed they will need less feet of wire to the frame.

In the present issue, Mr. Heddon is of the opinion that, were we to try his reversible L. frame on a large scale, we would like it better. While his frame would reverse a little quicker, perhaps, I should have this objection to it; namely, that it has the wood corners, which I never liked in any frame. I suppose the ordinary tin corner could be attached to the Heddon L. reversible frame. If I can get to it I mean to try a few of these frames made on his plan for experiment, though I hardly see how any thing could be simpler than our reversible corners, or less liable to come in contact with brace-combs or propolis.

DOOLITTLE'S METHOD OF FORMING NUCLEI.

Further experiments upon the Doolittle plan of forming nuclei have not been so favorable. In fact, many of the *old* bees in that nucleus (see p. 551) which I thought were successfully domiciled in their new quarters have since disappeared, and I suppose went back to their old quarters. Another nucleus was formed in exactly the same way, as recorded on page 551. When the bees were removed from the cellar, and put into the hive the following morning, their weight was two pounds and a quarter. On the morning of the second day the bees were shaken into a cage, and weighed. The result showed that the nucleus had lost a pound and a half of bees. Surely a part, at least, of these bees must have gone back to their old location. On looking into the hive afterward, although their numbers seemed depleted somewhat, I should hardly have supposed, judging from the looks only, that they had suffered such a loss. Some of the old ragged-winged bees were there, and are still there, showing that these old bees do not always go back, though it would appear that a large majority do.

I conclude, then, that, to correctly report upon the Doolittle plan of forming nuclei, the bees must be weighed before and after being moved. Had I done so in the first experiment, the results might have been similar to the last. The plan works nicely for introducing queens; that is, so far as tried; but from my present experience I should say that nearly half of the bees go back to their old location. Perhaps friend Doolittle can inform me why I have seemingly failed upon further experiments.

I will say this much, however: In experiments which we have made in forming nuclei in the ordinary way (i. e., taking frames and adhering bees from several different hives and uniting them into one swarm in a new location) we found that not a single ragged-winged bee would stay, though at least half the bees of the new-made swarm were of this latter class. With Doolittle's plan we did succeed in making a few, at least, of these old fellows stay at their new location.

ROBBING—A CAUTION TO BEGINNERS.

Our honey season has stopped suddenly off with us, and, in consequence, the bees are a little inclined to be cross, and rob. As many of our colonies are nuclei, we have to exercise extra precaution when opening and examining into the same. We are contracting the entrances of all such, and the boys are keeping a close watch of the whole apiary besides. When bees once get started to robbing badly at this time of the year we do not recover from the effects of it for the whole season; that is, when the little scamps have once learned the trick of thieving they do not seem to forget it soon. Beginners especially, need to be careful.

PUTTING A PANE OF GLASS IN FRONT OF THE ENTRANCE WHEN ROBBING HAS COMMENCED.

Seeing it recommended in the *British Bee-Journal* of the last issue, that an ordinary pane of glass placed in front of the entrance of a robbed colony would stop robbing, I determined to try the plan on some nuclei where a few straggling robbers were trying to gain entrance. These nuclei had just been opened, and, as usual just at this time of the year, robber-bees were around; and when the hives were closed they would pounce down upon the entrances, where the little lovers of home met them in hand-to-hand fight. Panes of glass were leaned against the front of two or three of the hives. The result was quite satisfactory; the robbers would either bump their heads against the glass, or, seeing their own image reflected against them, appeared to think that they were met by their enemies on the wing. Not many of them had sense enough to go around the edges of the glass; and the few that did, finding themselves inclosed, buzzed up and down the pane of glass on the inside, and finally dropped in front of the entrance. Here the inhabitants made short work of them. Very soon the robbers came to regard that entrance with evil forebodings; and when the glass was taken away they did not seem to know the difference. As to whether the glass will stop a bad case of robbing at the entrance when the inmates of the hive have given up in despair, I have my doubts; though the plan, if taken in time, might *prevent* robbing in a great many cases. ERNEST.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

MEDINA, JULY 15, 1886.

If any man walk in the day, he stumbleth not.—JOHN 11: 9.

THE FAVORITE PACKAGE FOR 100 LBS. OF EXTRACTED HONEY.

THE new square tin honey-cans are having quite a boom, and we are glad to see them going off thus, because we believe it is the best package for storing and shipping extracted honey we ever offered for the money, and we feel assured they will take well. If you haven't seen them, send 90 cts. and we will send you a pair of the cans, boxed, ready for shipment. As many of you have large quantities of extracted honey, it is time for you to be thinking of putting it in some suitable package.

CARNIOLANS AND THEIR MARKINGS.

I FIND that I made an error in a recent issue, stating that Carniolan worker-bees from our best queen received from Frank Benton were some of them yellow-banded. One of them produced part Carniolan workers and part workers having some of the yellow bands. We thought last fall the other Carniolan queen did the same thing; but at present we find no yellow-banded bees among the young bees just hatching out. There are Italian workers through the colony, but these probably came from adjoining hives. I am very glad to make this correction. The progeny of this Carniolan queen are, however, so near like common black bees that, when these common bees are flitting about the hive, trying to rob, we find it very difficult to tell one from the other.

REDUCTION IN THE PRICE OF SECTIONS DURING THE FALL OF 1886.

FOR the benefit of the prudent ones who may wish to purchase their sections this fall for next season's use, we have concluded to name the following very low prices for large orders; viz.: Regular Simplicity sections, $4.00 per 1000; 10 or more thousand, $3.50 per 1000; 100.000 or more, $3.25 per 1000. This will give supply-dealers a chance to be fully prepared for next season's orders, and will also give them a good fair margin for handling and paying interest on their money. We are also prepared to give low figures on almost every thing else to be ordered between now and the first of January for next season's use. We do this in order that we may keep our regular hands, instead of dropping them until business shall commence again. I would say, however, this reduction in the price of sections applies *only* to regular one-pound *one-piece* 4¼×4¼ sections. One-pound four-piece sections, either dovetailed or nailed, will remain at the old price, $4.50 per 1000. Odd sizes, up to 66 cubic inches, $5.00 per 1000. No order taken for less than 500 of an odd size.

A WHOLE YEAR OF GLEANINGS FOR ONLY 15 CENTS.

In looking over our stock of back numbers of GLEANINGS we discover that we have about a thousand bound volumes for the year 1876 still left. Each volume is securely bound with two brass clasps, and a complete index makes the whole convenient for reference. To reduce this stock we have concluded to dispose of them to our customers for the very low price of 15 cts. each, or 10 cts. additional when sent by mail. In this year you will find articles from the pens of Langstroth, Katie Grimm, Adam Grimm (who, with the money he made of his bees, established a bank), and a host of others whose active brains still live in the pages of these back numbers. On page 52 of this volume is an article written by "Novice," when he had the bee-fever, telling "How to Do Every Thing that Needs to Be Done with a Colony of Bees." In short, it is the A B C of bee culture in a nutshell. This article alone will be well worth the price asked for the whole volume to the beginner, as it covers all the questions that he would be likely to ask. On page 274 is described, by the aid of diagrams, how to make the chaff hive. All through the whole volume "Our Own Apiary" is full of practical hints.

RUBBER STAMPS FOR PUTTING THE NAME OF THE PRODUCER UPON SECTIONS OF HONEY.

Now that the honey season is about over, and the comb honey ready to come off, our friends will need some ready means of labeling their section honey. We keep and advertise labels suitable for the purpose; but the chief objection to this method of marking honey is the labor involved. Moreover, the producer could hardly afford to paste labels upon a ton of section honey, and a label pasted upon the clean white surface of a section does not, to our notion, really add to its appearance, although it will "set off" honey in jars or pails, and comb honey in pasteboard boxes. To meet the requirements of some cheap and rapid means of marking sections, the manufacturers of rubber stamps have made for our trade some very pretty designs of their work expressly for stamping the surface of sections. What can be more neat and tasty than the producer's card artistically lettered in red ink, stamped right upon the clean white surface of the basswood section itself? The freshness of the wood marked in this way produces an effect that can not be accomplished with paper and paste; moreover, the producer's card upon every section is a guarantee of itself that the honey is pure; and when the honey is extra fine, the consumer, whether he purchases much or little, knows right where he can obtain more of the same brand—a means of advertising of no small consequence. Why, I believe I should like the fun of stamping my name upon some of my own honey that I was choice of. We can furnish you a stamp of this description, packed in a neat tin box, necessary pads, and ink included, for $2.00, postpaid, or the same a little fancier, for $2.50. Send for our rubber-stamp circular, free on application, and you can then pick out the design you want.

THOMAS HORN, OF SHERBURNE, N. Y.

THE first advertisement sent us by this individual appeared in our issue for Aug. 1, 1885. He there offered very low prices on queens, in order to introduce his strain of bright Italians. A sample nucleus was sent us some time last fall, to let us see what we thought of his bees. Of course, they were very fair; and as his postmaster and banker seemed to consider him an energetic, go-ahead man, we continued his advertisement until June 1, of this year. At that time we declined inserting it any longer until he had straightened up complaints. Of course, Mr. Horn might have had so many orders that he was unable to fill them all; but with many orders, of course comes much money; and he certainly should have returned the money when he found himself unable to fill the orders—at least, so to seems to me. The operation seems to be a good deal of a repetition of the Herbert A. Burch swindle. If I am doing Mr. Horn an injustice, I stand ready to correct it any minute when he returns the money or fills the orders. Filling orders (for which cash was sent before the honey season opened) after the honey-flow is past, is not, of course, exactly the thing for a straight man to do; but I presume most of his customers would be glad to get even that, if they can't get the money. In justice to him, I would say that many orders have been filled after a long delay. In a few cases he has sent more than the money's worth. The question naturally arises, Is he responsible, and can these small sums be collected of him? So far as we have been able to gather, I think he is not—at least he allows his accepted drafts to go by without scruple. These operations have not been on any thing like the scale of Mr. Burch; that is, no very large sums of money have been sent him, so far as I can discover. When we accepted his advertisement he was considered a good square man; and whether this has all been a scheme of his from the outset, or whether he has used money belonging to others injudiciously, may be hard to say. At any rate, if he values his reputation we offer him every possible chance to regain it. The plea made by a few, that one may be swamped by reason of having *too much* business, is, I believe, recognized as being a rather thin excuse for neither sending back the money nor filling orders. Not a word has been heard from him since the telegram given in our editorial last month, on this matter.

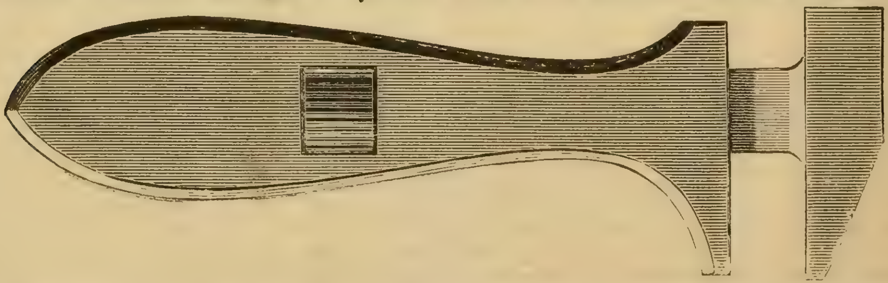
KENTUCKY QUEENS. Italians, Holy-Land, and Albinos. Tested, $2.00; untested, $1.00 each. Bees, 75c per pound after 15th July. PELHAM & WILLIAMS,
13-16db Maysville, Ky.

OUR TEN-CENT ADJUSTABLE WRENCH



The above cut gives the exact size of this very convenient tool, for the very insignificant price of only 10 cents. If wanted by mail, 6 cts. extra for postage. One of these wrenches in your pocket will oftentimes save you the cost of one in a single day. Who has not had to stop a plow, cultivator, or, possibly, some more complicated piece of machinery, while he went to the tool-house or somewhere else for an adjustable wrench? A good many times two wrenches are needed—one to hold the square head of a bolt from turning while you turn the nut. In such a case these little fellows will do just as well as a larger one. It is true, they are not strong enough for heavy work; but if you break them, why, you are only 10 cents out, after all.
A. I. ROOT, Medina, Ohio.

HARRINGTON'S AD.

BEES CHEAP!

I have the finest lot of Queens and Bees I have ever raised in my 13 years' experience, and should like to have everybody see them. I will sell at following low prices:

Farnumsville, Worcester Co., Mass.

WANTED.—To exchange bees or queens for foot-power saw. Will sell fine tested queens for $1 each; untested, 70 cts. each, either Syrian or Italians. ISRAEL GOOD, Sparta, Tenn.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have some Italian hybrid queens that I will mail at 30c each, and guarantee safe arrival.
N. A. KNAPP, Rochester, Lorain Co., Ohio.

24 hybrid and mismated queens for 40 cts. each; 3 for $1 00; also a few untested and tested queens, rather small, but good layers, at same price. Safe arrival guaranteed. S. C. PERRY,
Portland, Ionia Co., Mich.

Good serviceable hybrid queens, one year old, for 25c each. Ready now. J. H. JOHNSON,
Middaghs, Northampton Co., Pa.

I should be glad to sell what black queens I have for 25c., and hybrids for 50; ready now.
ADOLPHUS NEWTON, Plymouth, N. Y.

Wishing to Italianize my whole apiary I have a few hybrid queens for sale at 25 cts. each. They are all prolific, and the workers gentle and good.
WM. H. HUSE, Manchester, N. H.

HYBRIDS AT $3.00 PER COLONY.

Must be sold prior to Aug. 25th, 25 colonies of bees, in frame hives; plenty of honey to winter, only $3.00 each. I am going to Pacific Coast. 14-15d
Address H. H. WINSLOW, Liberty, Clay Co., Mo.

ITALIAN QUEENS, by Return Mail, Tested, $1.00. Untested, 75 cts. Bees, 50 cts. per lb.
14-15d GEORGE STUCKMAN, Nappanee, Ind.

Stop! Read This!

12 warranted Italian queens, by return mail, for $8.00; 6 for $4.25. Single queens, 75 cts., after Aug. 1. Carniolan queens at double the above price. See our advertisement on another page.
J. B. MASON & SONS,
14d Mechanic Falls, Me.

CELERY-PLANTS.

Crawford's Half-Dwarf, Boston Market, etc., 150 choice plants, carefully packed in a box and mailed prepaid for $1.00; 1000 for $4.00. Safe arrival guaranteed, even to California and Oregon. By express (not prepaid) just half above rates.
A. T. COOK, Clinton Hollow, Dutchess Co., N. Y.

BEE-VEILS.

WHEN the honey stops coming in, perhaps some of you will need a good bee-veil. We can furnish you a well-made veil of grenadine, with a face of Brussels netting, for only 50 cts. postpaid; 10 for $4.00. Our former price on a veil with a facing of Brussels netting has been 75 cts.
A. I. ROOT, Medina, Ohio.

DR. J. W. CRENSHAW, Versailles, Woodford Co., Ky., has untested Italian queens for sale at 75 cents each. 14-15d

$2.50 CHEAP $2.50

I will sell three-frame (Simp. size) nucleus colonies, all straight worker-comb, well-filled with brood and honey, 1 pound of Italian bees, and nice tested Italian queen, for only $2.50. Now, friends, I guarantee these colonies to be first-class in every respect. Fifty colonies ready now. A fine lot of untested queens at 75 cts.; $4.00 per ½ doz., and tested at $1.00; $5.50 per ½ doz. Safe arrival and satisfaction guaranteed. **F. W. MOATS,**
14d The Bend, Defiance Co., Ohio.

CONVENTION NOTICES.

The next meeting of the Stark Co. Bee-Keepers' Society will be held in Grange Hall, Canton, O., Aug 31, 1886.

MARK THOMSON, Sec.

The Committee is hard at work perfecting plans for the next Annual Convention of the N. A. B. K. A., to be held at Indianapolis, Oct. 13, 14, and 15, 1886, and will soon be ready for the general announcement of programme, etc.

DOUGHERTY & WILEY, Indianapolis, Ind.

KIND WORDS FROM OUR CUSTOMERS.

HOW WELL OUR EXTRACTOR PLEASES.

We received the extractor last Saturday, the 19th. It works splendidly. We have already extracted enough honey to pay for it, if we can get a fair price for it. Mr. Root, you can not know how thankful we are to you for sending it without having received the money; for if we had been obliged to wait until we had the money to send, the honey season would have been almost past; and all such favors in the past and future have been and will continue to be highly appreciated. MILLER BROS.

Bluffton, Mo., June 26, 1886.

CARNIOLAN ✻ QUEENS.

Carniolans are the Gentlest Bees Known,

AND EQUAL TO ANY OTHER RACE FOR WORK.

THE QUEENS ARE THE MOST PROLIFIC.

I offer daughters, of Imported Benton Carniolan queen, raised in my apiary of 40 colonies of pure Carniolan bees, during the remainder of this season, $1.00 each; six, $5.00.

DR. S. W. MORRISON,
13tfdb **Oxford, Chester Co., Pa.**

ITALIAN QUEENS FOR 1886

Tested, 90 cts.; untested, 50 cts.; warranted, 65 cents.

C. C. KIRKMAN,
15d Coxville, Pitt Co., N. C.

RED-CLOVER ITALIANS.

During the season just passed, Moore's Italians have roared away on red clover, in countless thousands. Reduced prices: Warranted queens, each, 80 cts.; per ½ doz., $4.50. Tested queens, $1.50. Safe arrival and satisfaction guaranteed. Circular free. 15tfdb J. P. MOORE, MORGAN, PENDLETON CO., KY.

Jerseyvile, Ill., July 23, 1886.

Mr. J. T. Wilson, Dear Sir:—The 55 warranted queens I received of you last year were all purely mated except one. The most of the queens were choice, and as good as higher-priced ones, for general purposes. E. ARMSTRONG.

One queen, 75 cts.; 6 for $4.00. Warranted purely mated. Will work as well on red clover as anybody's bees. Will exchange for honey, alsike clover seed, or Poland-China hogs.

15d J. T. WILSON, Nicholasville, Ky.

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ad's intended for this department must not exceed 5 lines, and you must SAY you want your ad. in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates.

WANTED.—To exchange 20,000 strawberry-plants, Crescent Seedling, Cumberland Triumph, Sharpless, and Glendale, 75 cts. per 100; $4.00 per 1000, for bees, foundation, or improved poultry.
10tfdb W. J. HESSER, Plattsmouth, Neb.

WANTED.—To sell, after June 1st, 50 3-frame L. size nucleus colonies of hybrid bees, with queens, for $3.50 each, delivered at Plattsmouth, Neb., or I will exchange for young stock, cattle or horses, or apiarian supplies.
12tfdb J. M. YOUNG, Rock Bluff, Cass Co., Neb.

WANTED.—A partner to take half-interest in an Apiary, with a little capital. Address
LOUIS WERNER, Edwardsville, Ill.

FOR SALE.—Pasteboard boxes for inclosing section honey. The best out! Improved over last year. Thousands sold! Price, 1-lb. size, $6.00; 2-lb., $8.00 per 1000. One sample, 5c. 14-oz. square glass jars, $5.00 per gross; 1½ gross in case. Fine assortment of honey labels. Catalogue free.
14-17db A. O. CRAWFORD, S. Weymouth, Mass.

WANTED.—To exchange bees or queens for foot-power saw. Will sell fine tested queens for $1 each; untested, 70 cts. each, either Syrian or Italians. ISRAEL GOOD, Sparta, Tenn.

WANTED.—To exchange Italian queens for alsike clover seed. J. T. VAN PETTEN, Linn, Kan.

FOR SALE.—A two-story brick house, with five lots, good barn, ice-house with cooling-room, bee-house, honey-house, wood-house, etc. Grapes, berries, apples, and cherries on the place; in small town, location suitable for bee or chicken business. Will sell cheap for cash, or exchange.
15-18db ANABEL RONALD, Grand View, Iowa.

WANTED.—To exchange a warranted first-grade fruit and vegetable evaporator and baker, for honey—a bargain for an orchard owner.
15d JNO. C. CAPEHART, St. Albans, W. Va.

WANTED.—To exchange best drone-traps made for one or more extractors, Simplicity frame. Send for circular.
15tfdb J. A. BATCHELDER, Keene, N. H.

WANTED.—To exchange for comb or extracted honey, cash or offers, 15,000 pot-grown strawberry plants of the best varieties; also game cocks. Can give best reference. GEO. M. WERTZ,
15tfdb Johnstown, Cambria Co., Pa.

WANTED.—To exchange hybrid bees, in 10-frame Simplicity one-story hive, with 10 frames full of brood and honey, for incubator, printing-press, Pekin ducks, or B. L. pullets, or any thing useful. Write at once, saying what you have for exchange.
15-16 Address JNO. W. MARTIN, Greenwood, Va.

WANTED.—To sell or lease a farm, 160 acres in cultivation, good buildings, good water, an apiary of 75 colonies in Simp. hives, carp-ponds, etc.
15-16d A. W. MATTHEWS, Galla Rock, Pope Co., Ark.

FOR SALE, or will exchange for 20 two-story Simplicity hives, complete, in flat, golden Italian queens. Price, mismated, 50 cts.; untested, 75 cts. Tested, $1.50; best select tested, one year old, $2.50. Safe arrival and satisfaction guaranteed. Reference, Bank of Princeton, and L. Goodwyn, P. M., Frenchville, W. Va. L. L. HEARN,
Frenchville, W. Va.

WANTED.—To exchange full colonies Italian bees for first-class bicycle, 50 inch, or first-class double-barrel breech-loading shot-gun, 10 or 12 bore.
15 D. S. BASSETT, Farnumsville, Wor. Co., Mass.

WANTED.—To exchange strawberry-plants, Crescent, Big Bob, and Clark's Seedling, for alsike clover seed or money. MAHALA B. CHADDOCK,
15d Vermont, Fulton Co., Illinois.

HARRINGTON'S AD.

BEES CHEAP!

I have the finest lot of Queens and Bees I have ever raised in my 13 years' experience, and should like to have everybody see them. I will sell at following low prices:

SELECT TESTED (VERY FINE) $2.00
TESTED - - - - - - - 1.00

My Queens are nearly all mated with drones from an imported Italian Queen. Half-blood Holy-Lands, Cyprians, and Albinos, at same price.

YOUR "OWN APIARY."

SOME SUGGESTIONS FROM FRIEND HEDDON.

AS Ernest is now the practical apiarist at the "Home of the Honey-bees," perhaps I can shed most light by discussing with him the more vital and practical points connected with our pursuits. Now a word about

REVERSING.

In enumerating some of its advantages, on page 593, Ernest has omitted one which we prize most highly. It is this: When a frame is completely filled with comb, leaving no lurking-places, we can quickly clear it of all bees for extracting or other purposes, and more readily find the queen when traversing such combs. He says, truly, that the metal corners could be attached to the Heddon reversible frame; but, how differently we look at these things! I could not be induced to use metal corners under any circumstances. I find them liable to bend, and are cutting to the fingers when handling and shaking the combs. The common wooden projection is very readily movable when placed upon metal rabbets, and we use such in all our extracting supers, but have entirely discarded these rabbets in the brood-chamber; for as we handle hives more and frames less, we do not want the frames to slide about so easily. We so used 25 hives for three years.

Is it not true, that our older producers are likewise discarding metal corners for frames? Metal standards are not needed in our frames, because the top-bar is double; and there is nothing to even tend to sag the outer bar, which determines the accuracy of the bee-space. If the inner bar sags, it straightens again after inversion.

The large open space which our style of frame leaves between the hive and the lower half of the frame-end, aids much in removing and readjusting it. The outer top-bar must be firmly nailed to the outer end-bars to prevent pulling off when shaking heavy combs, as it is not fastened to the comb. I suggest two proper-size barbed wire nails at each end; and we use and prefer whitewood or poplar for these end-pieces.

ROBBING.

Let us try having that pane of glass a looking-glass, and see what effect that will have. Perhaps not as good as plain glass, but we might try it.

EMPTY BROOD-NESTS.

Friend Hutchinson, it appears, is carrying this problem all alone. Almost every day I receive letters declaring against his position, citing experiments as well as theory. The basic principle of friend H.'s departure, I advocated some years ago as between empty frames or frames of foundation and full complete combs, when running for comb honey. I did not at the time, and can not say that I do now, conceive that this principle reaches so far, that empty frames are even more profitable than frames filled with foundation, at the same price, when running for comb honey. But I have not experimented directly upon this point, and friend H. has, and he is an apiarist in whose integrity and practical knowledge, as well as keen insight, I have the greatest faith; in fact, my acquaintance with him compels me to say that I hold him second to no man in America; and this, coupled with his vigorous pen, accounts for his shooting up above the apicultural horizon like a meteor. While such great "doctors" disagree, and while I am confident that both sides are right, in part, next season I am going to test this important problem for myself and my surroundings, in hopes to become an ally or an experienced opposer of friend Hutchinson's. It is a great problem, directly affecting the economy of our pursuit.

OUR 1886 MARKET.

Hold on, friend Root! "schtop a leedle;" somewhere in last issue you spoke of the low price we were going to get for our 1886 crop of honey. Notwithstanding my wide correspondence with bee-keepers, and careful watching of this point in the journals, I am unable to see any cause for said "low prices," unless it be statements like your own referred to. In very many localities in the U. S., this year's crop is almost or quite a total failure. In many others the white-clover crop is good; but so far as I can learn, the basswood, the greatest yielder of them all, is not even a fair crop, except in rare instances; and, taking the whole country together, may be pronounced almost a failure. Now, why should we look for prices lower than those of last year? Let no man so consider it until evidence compels him to. Let me tell you why. Honey is essentially a luxury; a large portion of honey-consumers would buy nearly or quite as much at a high price as they could be induced to consume at any price. Last year's prices were as low as bee-keepers can thrive at, and I firmly believe that if all who have honey to sell will take courage and advantage of the pitiful fact that many of our brothers have none at all, there will be no trouble to find a demand for the 1886 crop at prices equal or better than those realized last year.

FORMING NUCLEI.

Ernest's last report of his experience with the Doolittle method is just what what we should expect here. Had he met the same success reported by Mr. Doolittle, we can not then see any reason for adopting that method. We have this season formed some 300 nuclei, and in our next will tell you how we succeed, to our entire satisfaction with (we think) less than one-fourth the labor and trouble necessary to the carrying-out of the Doolittle plan.

Dowagiac, Mich., July, 1886. JAMES HEDDON.

I am very glad if honey will not have to go at a low price, friend H.; but I judged so because so many are wanting to sell us honey while we are so well supplied that we can not make even a decent offer for it. Now, the best remedy I can think of in the line of your suggestions is to keep our Honey Column full. Will our brethren who have honey to sell tell how much, what quality, and what price they want, so that we may put it in the Honey Column? I think those who advertise in that way usually make sales sooner or later. We presume you all know that such notices are printed free of charge. —In regard to metal corners, I think that those who raise queens as we do will generally prefer them. With the constant manipulation in our apiary, we could not think of having combs that must be pried loose before they can be handled; and as our combs seldom get very heavy with honey, they give little or no trouble in the way of cutting fingers.

I tried the looking-glass, but not with so good results. The plain sheet of glass, by reason of its transparency, does not alter the appearance of the entrance; and the robbers, being deceived, will worry and weaken themselves in much the same way that they do in trying to get through our windows. On further trials, however, although the glass in many cases will answer a very excellent purpose, I think I should prefer to contract the entrance as is ordinarily practiced to prevent robbing. I have found that the glass will worry the occupants of the hive as well as the robbers, and also, as it is a little inconvenient to carry the glass about, the boys do not use it. It did not occur to me that the bees could be shaken off more easily, and the queen be much easier found, when the frames have been reversed. I see no reason why it should not be so.

MELILOT, OR SWEET CLOVER, AS A HONEY-PRODUCER.

FRIEND MUTH GIVES US SOME DEFINITE FACTS IN REGARD TO THE QUALITY OF THE HONEY.

FRIEND ROOT:—For the first time since I kept bees, our honey harvest has kept up, apparently, through the month of July. We never had so abundant a supply of melilot, or sweet-scented clover, as we have this year. Every hilltop and vacant lot in and about our city seems to be covered with it, and it is swarming with bees. They do their work quietly and steadily. Passing along a road a few days ago, which was lined with melilot, I stopped my wagon and went in. It was alive with bees, steadily at work. I was surprised, as I did not notice any bees while driving along. So far, melilot has furnished only enough honey to keep bees breeding until late in the fall, while now we get a surplus, which may last until frost comes.

The month of June, in this part of the country, is or has been our honey month, as with it white clover begins and ends, which used to be our whole resource. Cold nights during the first half of last June prevented the secretion of nectar; and wet weather during the latter half damaged our crop. I don't think that 25 lbs. of white-clover honey per colony is produced in the States of Ohio, Kentucky, or Indiana.

To-day's mail brings you a sample of melilot honey, which is produced on one of our hilltops on the west side of our city—Price's Hill. It is a fair sample of my own honey, and of that of a friend who lives at Clifton Heights, which is a hilltop on the north of our city. These three samples being alike, I have reason to believe that the sample mailed you is true melilot honey. The honey is very sweet, flavor fair, though not as good as that of white clover. It has a good body, but a color as if it were mixed with soot. Such honey will never answer to be put in the market for table use. The color of the honey is much stronger shown in a larger bottle than the one mailed you. This small bottle, however, will answer the purpose, if you hold a small bottle of white-clover honey alongside of it. If I am correct as to the source of this honey, melilot will be a great disappointment to us. I hope friends from other parts will report on the subject.

Cincinnati, O., July 17, 1886. CHAS. F. MUTH.

Many thanks, my good friend, for your kind letter, and the sample of honey. I should not be in haste to feel disappointed, for it occurs to me that the sooty appearance of the honey may be caused by the smoke of your great city, even if the clover does grow on the hilltops. You will remember that friend Kendel said, some time ago, that he would have to give up raising comb honey, by reason of the soot; and later I think he has said he will have to abandon liquid honey for the same reason. The flavor of the honey, I should call beautiful—in fact, I believe I should prefer it to honey made from common white clover—that is, at first taste. Now, can't some of the friends who have been raising melilot by the acre tell us if it always has a dark, sooty color? If melilot can be made available for some other purpose than the honey it produces, it seems to me it would be quite promising as a honey-plant.

A KIND REPORT FROM ONE OF OUR FRIENDS OF THE MINISTRY.

GETTING HOLES IN THE COMBS FOR WINTER, ETC.

MY DEAR BROTHER A. I. ROOT:—I thought I might venture a line in GLEANINGS, and thus in a small way reciprocate the kindness of others who from time to time have given to such as me encouragement and instruction. However, I shall not assume the *role* of instructor.

I began last season with one colony of Italians; increased to 3, but took no honey. They wintered nicely, in the main. The ones in the single-wall Simplicity—upper story filled with chaff, and protected on the west and north by a wall of empty hives—came through stronger, however, than the ones in the chaff hive. At the suggestion of Bro. James Walcher—an apiarist of not a little celebrity, located near Millersville, this State—in the Simplicity single-wall I cut holes through the combs near the top-bar, about one inch in diameter, that the bees might have easy access to all the combs, without passing around at the bottom, and thus expose themselves to the cold. I do not see but it answers the same purpose of Hill's device; and if so, dispenses with this much that would demand care and space. I did not accommodate the bees in the chaff hive with this "short cut," though in other respects they were the same; so I am persuaded that the holes were a decided advantage, and especially for a winter such as last.

This spring I procured 3 colonies more—Italians. Two of them were quite weak, so to start with I had 3 strong and 3 weak colonies. I have increased to 13 colonies, and have taken, with the aid of the Novice extractor, 953 lbs., and 96 lbs. in 1-lb. sections, making in all 1049 lbs.

We had an ideal spring, and the summer thus far has been uncommonly fine. We have had flowers in profusion, and the flow of nectar has been most copious. The white clover and linden have both yielded profusely, and now the mustard and smartweed are making yellow and pink every nook and corner, and all these flowerets seem to be doing their best, so the busy bees are still invited to sip, and will continue to provide, for weeks to come, I doubt not, these delicious juices.

While it is my chief concern to herald the glad tidings of God's full and precious Christ to poor lost ones, I can fill up the spare hours most happily in looking after the bees, and I am made to sing from a full heart at each new unfolding, "How good is the God we adore!"

I have found the A B C book and Cook's Manual valuable aids; they have helped me through many a perplexity. I may add, I began with gloves and veil, but I have dispensed with both.

The 10-cent honey-knife is just the thing. It has done all our uncapping. FRANK C. BLOUNT,

Lawndale, Ill., July 14, 1886.

Thanks, friend B., for your kind letter. Some years ago it was quite common to cut these winter-passages; but the bees often seal them up during a good honey-flow, and some of the friends think it makes the combs look unsightly. Another objection is, sometimes the cluster is over at one side of these holes, and they don't answer the purpose. To obviate this latter, two holes have been suggested, 3 or 4 inches apart; but as the Hill device, or some equivalent, permits the bees to pass out and around, and does not mutilate the combs, we have rather preferred it.

IMPROVING OUR SEED BY CAREFUL SELECTION OF STOCK.

SOME KIND WORDS FROM THE OHIO AGRICULTURAL EXPERIMENT STATION.

FRIEND ROOT:—I have been quite pleased in looking over your journal of the 15th, to see what you say about selecting seed. I have been working in this line here at the station for some time. I have not done much toward the improvement of vegetables, except tomatoes; but I have tried to show the importance of selection, as you may have seen in our report. The character of stock from each seedsman is there commented upon. This has not been undertaken for the purpose of exposing the poor stock of any one in particular, but rather for the purpose of calling attention to the importance of *selection* in growing seed. We shall continue the work, and enlarge upon it as fast as possible.

My purpose in writing this is to call your attention to the excellence of Mr. Brill's cabbage-seed, especially that of his Early Wakefield. I regard it as the best to be found in the market. Under favorable conditions I am sure that 95% will form marketable heads, and they are remarkably uniform. If you refer to me, perhaps Mr. Brill will send you a better grade of stock than he otherwise would, as he has, as all growers have, what they call stock seed, also ordinary trade seed. He may send you some stock seed. His Early Summer is also excellent, as are all his cabbage and cauliflower seed. Have you tried the Deacon lettuce? If not, Joseph Harris has it. You are doing a good thing for the public in showing what may be done in gardening. W. J. GREEN.

Columbus, Ohio, July 19, 1886.

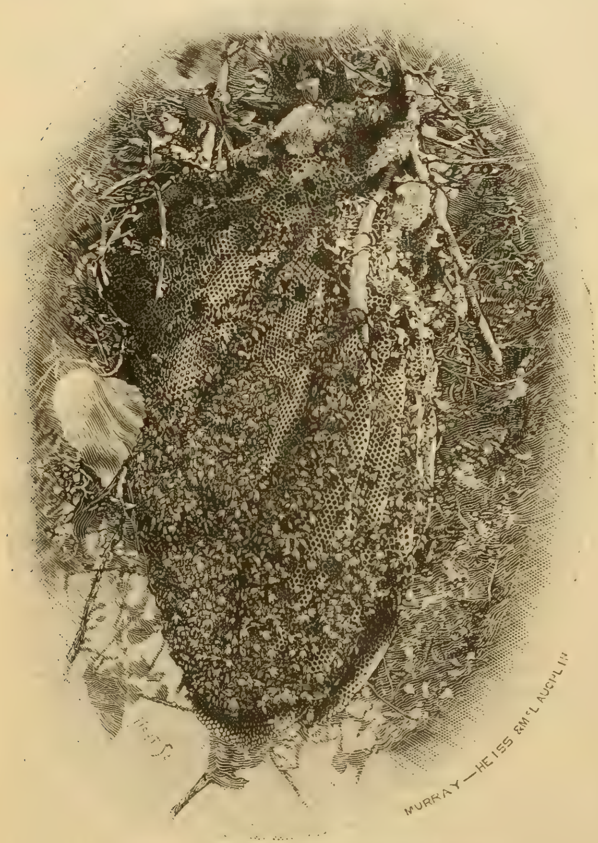
Experiment Grounds at the Ohio State University.

Friend G., I presume your kind letter was not intended for publication; but as it will be read with interest, I am sure, by many of our readers, I take the liberty of giving it here. I have never tried the Deacon lettuce, but I will order some at once, and perhaps many of our readers will be glad to avail themselves also of the opportunity. I have had you and your work in mind, friend Green, all along in my work at seeds and plants.

HOW BEES WORK IN THE OPEN AIR IN CALIFORNIA.

A PICTURE SENT US BY THE KINDNESS OF FRIEND HILLIER.

WE have frequently had reports of bees building combs in trees or among bushes, and living for several months, even where rainstorms are frequent. We have also been told, that in California and other countries where no rain falls for a long period, and comparatively little in the rainy season, that they would live the year round in no hives except the protection afforded by such combs as they could build, and by their own clustering, shedding the rain with their wings turned like shingles. Below we give a picture of such a hive.



A COLONY OF BEES LIVING AND PROSPERING WITHOUT A HIVE.

The following is all the description we have with the picture:

I mail you a stereoscopic view of a swarm of bees at work in the open air, which is no very uncommon sight here. They are hybrids. H. H. HILLIER.
Pasadena, Los Angeles Co., Cal., June 9, 1886.

We think our engravers have done a pretty fine piece of work in copying so faithfully the work of the camera.

A CALIFORNIA BEE-STORY.

TRUANT SWARMS GOING INTO HOUSES IN CALIFORNIA.

I MAY have told you about my brother who lives on a ranch near San Diego, Cal. Well, this brother has never taken much to bees, but lately he has got a notion of trying them. He gives us some of his experience in the following; also the bee-story alluded to in our head:

Bro. Amc:—Last January I bought 4 stands of bees for $10. As they were in common box hives I transferred them in February, the weather being so warm the combs all ran together, and, I think, destroyed all the queens but one; and after swarming the hive lost its queen, I think, as it is not doing any thing. I put a hive up by the barn, put ten frames in with fdn., and in a few days it was full of bees. I moved it down to the yard, and now they have the frames all capped, and part of the sections filled and capped. I fitted up another hive in the yard as above, and got them full of bees the same as those at the barn. The old original swarm is not doing any thing. Had I better have a good queen?

I imagine the bees here are mostly hybrids, although mine show three yellow bands. During May and June there were swarms passing over almost every day, and some of my neighbors have a good deal of trouble in keeping bees out of their houses. They have asked me what to do to get rid of them.

One Capt. Keen, from New Orleans, left his house here vacant one season; and when he came back he said he noticed his house was settling, and he thought it strange, as he had a good brick underpinning. Finally he went up into the garret, and found it full of bees and honey, and he says he has sent off for teams, there not being enough in this neighborhood, and has taken off 50 tons of honey to San Diego, and has got only a very small part of the whole yet. He says he has glutted the market, so now honey is down to 3 cts. a pound.

The above corresponds with one of his stories. He says he tells them in New Orleans about California beets. Where the beets are taken out of the ground, he says, we have to build a fence around the hole to keep the stock from falling in.

Joking aside, the country around is full of bees. I know of several places where they are in caves on the hills. If I had been at home, so I could have attended to them, I have no doubt I could have had ten stands. Mine are very cross, but I rather like them. I think, as you say, bees are very good-natured.

There is a near neighbor of mine, Mr. Little, who keeps 250 stands in common boxes, with a stick across and box on top; and when the top box is full he empties the contents in a solar extractor, and sells wax and honey. I am told he got $800 for his wax and honey last year. He says he does not know any thing about bees.

I stayed with Capt. Knowles, on the San Diego River, last winter. He says there is more clean cash in bees here than any thing else, if a man understands it. He does not fuss with them as much as you write about. If a swarm gets weak he lets them go. He says his time is worth more than the bees. He uses part Simplicity hives and part Harbison's; but he likes the Simplicity the best of all, and would use all Simplicity but it is too much work to transfer them. He has three apiaries, and I think about 1000 swarms. I am situated so I think I can keep about 200, with plenty of room for forage.

I am going into the "New Agriculture" some. I am never so happy as when I have domestic pets and plants and vegetables growing. I can almost compare my "mountain retreat" to Robinson Crusoe's island. M. S. ROOT.

San Diego, Cal., July 11, 1886.

BOOK-REVIEW DEPARTMENT.

COOK'S MANUAL OF THE APIARY.

I SHALL not attempt to give a review of the whole work, but will confine myself to the new matter which has been added, or, rather, as I judge, substituted, in place of something else. If I am correct, there are about 25 pages rewritten in the new edition, the major part of which pertains to the

HEDDON-LANGSTROTH HIVE,

how made, and how to use. This is the hive that the professor has tried, and *knows* to be practical. After enumerating its good features, one is made to feel almost sorry that Heddon did not let well enough alone, and stay content with his old hive; but as Prof. Cook follows the safe rule of never recommending what he has not tried, though recognizing in theory the good points of the new hive, it is easy to see why he speaks in praise of the old hive. Of it he says:

> Thus I have described the Heddon-Langstroth hive minutely, as with W. Z. Hutchinson, W. L. Taylor, and many others of our most able and intelligent apiarists, I find it upon trial as excellent as it is simple. Surely, when we can harness excellence and simplicity together, we have a most desirable team. The simple union of parts by mere plain contact of the edges, or the cover simply lying on the hive, while it is just as acceptable to the bees, makes the hive far more simple of construction and easy of manipulation. The honey-board and bee-spaces keep all so neat, that, as one bee-keeper well says, their extra expense is very soon saved in the saving of time which their use insures. Any who may think of trying this hive had better do as I did, try two or three at first, and see if in their judgment the "game is worth the candle."

REVERSIBLE FRAMES.

Prof. Cook's experience with the principle of reversing frames in general, accords quite closely with ours as recorded in the department of Our Own Apiary of the two last issues, and I feel sure he is right when he says:

> For the past two years I have used the reversible frame which I find so valuable that I shall use it largely in future. With this frame there is no danger of the top-bar sagging, which is sure to enlarge the bee space above and create mischief, and by inverting we secure the firm attachment of the comb to the frame along all its edges, and can force our bees into the sections at the very dawn of the honey harvest. * * * * * These frames [Heddon's] reverse very easily, and I do not know a single person who has thoroughly tried them, who does not value them highly. Here again let me suggest that in making changes, a few be tried first, and not all till we know we wish them.

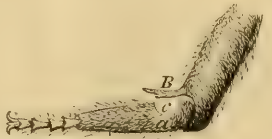
Notice in this and elsewhere, that he recommends trying only a few. While I *now think* that the advantages of the reversible frame are such as to ensure its ultimate adoption, nevertheless I regard the caution of trying a few first as a wise one. Many of us like the principle; but some of us, by reason of our difference in make-up, might not so regard it. Friend Pond, I believe, belongs to the latter class.

THE NEW HEDDON REVERSIBLE HIVE.

About three pages of new matter is devoted to this hive, and I will insert below what Prof. Cook says of it, omitting the description, which has already appeared in GLEANINGS. He says:

> Mr. Heddon has just patented and offered to the public a new hive which combines in principle the Langstroth and the Huber. I have never tried this hive, and so, guided by the rule I have always adopted, I do not recommend it. Yet the experienced bee-keeper can often judge correctly of what he has never tried, and I will add that I fully believe this hive, and the method he gives of manipulation in his valuable book, are well worth our attention. Mr. Heddon is so able, that he rarely recommends what is not valuable. Several others have tried this hive and speak in the highest terms of its value. Among these is no less an authority than W. Z. Hutchinson. At the beginning of this chapter I caution all against patent hives. This is necessary, as so many frauds have been committed under this guise; but if Mr. Heddon has given us something as valuable as it is unique and original, he well deserves a patent, which should be thoroughly respected, as should all worthy inventive effort.
>
> The points of excellence claimed for this hive, and I believe from my experience that they are valuable, are easy contraction of brood-chamber, quick inversion of the brood chamber or section case, ease and quickness of manipulation, and the interchangeableness of the brood chambers forming the hive, the power we have to get all light-colored honey in the sections if we so desire. Mr. J. M. Shuck has also patented a hive for which he claims the same advantages gained in the new Heddon hive. I have not seen this hive, but recognize in Mr. Shuck an able bee-keeper and a man of rare inventive genius.

On pages 88 and 89 is described the use of the curious little notch found in the fore legs. That our readers may better understand, we reproduce the cut, which appears below.



ANTERIOR LEG OF WORKER, MAGNIFIED.

This little notch, or flute, is shown at C; and in speaking of its use to the bee, the writer says:

> On the anterior legs of bees, between the tibia and tarsus, is a curious notch, C, covered by a spur, B. I have found this in nearly all Hymenoptera, except the saw-flies, where it is very abortive if present at all. This is principally used in cleaning the antennæ, as is easily proved by dusting these organs with chalk, pollen, etc. This cleaning of the antennæ is best studied by observing wasps. After scraping off the antennæ the leg is cleaned by drawing it between the mandibles, or between the joints of the middle legs.

In the previous edition, if I am correct, Prof. Cook was not certain as to the real use of this little notch, though he suggested that it might serve various purposes. To satisfy myself I dusted the antennæ of several bees with flour, and noted the results. The movements of the bees were so quick that I could not determine exactly how it was done. Whenever the antennæ, or feelers, were dusted, they were quickly cleaned; but how? With a magnifying-glass, after the antennæ were thus cleaned, I examined closely the little notch at C. It did not take long to discover there the wheat flour, which evidently had been scraped off the feelers. After repeated watchings, a bee finally moved his leg so slowly that I saw exactly how it was done. I further tested the matter by besmearing the antennæ with honey. The same result followed as before. As the power of delicate touch, and, by some authorities, hearing and smelling as well, is supposed to reside in the antennæ, it is highly important that these organs be kept perfectly clean by some such contrivance as that shown at C.

These, I believe, are all the important changes as made in the latest edition. It is to be regretted that the new matter has been set in a slightly different-faced type, rather marring the appearance of the page where the two kinds of type (though both are supposed to be "long primer") come together in contrast. This is brought about, I suppose, by the fact that the book has been printed at two different offices, each of which had its own kind of long-primer type. However, to any one not a printer, nor interested in printing, I suppose this difference in type would not be apparent.

ERNEST.

TROUBLE AT THE HOME OF THE HONEY-BEES

For the thing which I greatly feared is come upon me, and that which I was afraid of is come unto me. —JOB 3: 25.

DEAR FRIENDS, when I told you in our last issue that we had Canada thistles on our plantation, I had no idea that I should be obliged to chronicle, in a few days more, that we had foul brood in our own apiary. I have for many years feared that, sooner or later, something of the kind would happen, and I once told our good friend D. A. Jones that I could think of no calamity so dire as this. He told me not to worry, but that, if we ever got it, to write to him and he would come down and cure it for us for nothing. You know that is just like him for all the world. Well, we have not taken up this kind offer, for the reason that the disease as yet has made its appearance in only ten colonies out of over 400; besides, according to his description in his little book, "Foul Brood, its Management and Cure," it is not the real *virulent* foul brood, but what he defines as "'dead' brood." The larvæ die at different stages, and either become soft and pasty, or dry up in the lower side of the cell. The sealed brood has usually pinholes through the cap, but the cap is not sunken. The well-known disagreeable smell accompanies it, and this alone tells when it has got a foothold in a hive. Do you want to know what we have done? Just this: Every comb in every hive containing even a trace of it has been burned up by throwing them all in the furnace under the boiler of the engine. We are going to starve the bees until the contents of their honey-sacks are nearly or quite exhausted, then put them on good new combs. The hives will be thoroughly scalded by a jet of steam from a rubber hose. Meanwhile we will fill no orders for bees, queens, or brood, from our apiary, unless our customer has seen this sheet, and expressed himself willing to have his orders filled from our apiary from colonies that have never shown a trace of it. Orders as they come will be filled promptly, as usual, from the apiary of Neighbor H.

Now, then, how did it come about? I can not tell, unless it was from honey we had purchased — possibly from a leaky barrel; and this has decided us never more to purchase honey in barrels. It must be in tin cans; and should any leakage occur from these they are to be mended and washed before the bees can have a chance to gain access by any possible means to the outside of the cans. It may have been brought to us in another way. We are purchasing wax constantly, and it comes from almost every quarter of the globe. The wax cakes often contain more or less honey daubed on their surfaces, and sometimes a bee or two gets into the wax-room and goes to work on these wax cakes. By the additional room given us by the building of our new factory, we are going to have all wax taken in the original packages at once to a darkened room. The wax is to be so thoroughly protected, both by doors and windows with wire cloth, that no bee gets outside or inside alive. Some may ask why we should not cure the foul brood, instead of resorting to such destruction of valuable property. If I had only a few hives, and could give them my constant supervision, some such plan might answer; but as it is, I prefer to burn up every thing it has touched until no further trace of it can be found. We are going to treat it as we did the Canada thistles; and may God help us to conquer, for *your* sakes as well as our own.

I feel quite certain that there will be no possible danger of the disease being transmitted by selling queens, or even pounds of bees. It is, however, everybody's privilege to decline buying from an apiary where foul brood has existed, if you wish. In regard to the chances of contagion, even by taking queens from diseased colonies, we make the following extract from D. A. Jones's little book referred to above:

> I have never yet known the disease to be contracted by either queens or drones, although I have experimented largely in that direction, taking queens from foul-broody colonies and placing them in healthy colonies. I was once informed by one of the best bee-keepers in the United States that he had tried the experiment scores of times; that is, selling the queens out of healthy colonies, and replacing them with those from the worst affected foul-broody colonies, and in no instance did the disease appear in these hives, the apiary being three miles from the one in which the diseased colonies were. The gentleman had several bee-farms. I do not mean to assert that the disease *never has been* carried by queens or drones, but I honestly believe that if it *has ever been* the case, that the honey taken with them had *something* to do with it.

Please remember, friends, there is not a cell of foul brood now in our apiary—at least, none that we can discover; and every comb of our over 400 hives has been carefully scrutinized.

PREVENTING SECOND SWARMS.

TEN QUEENS IN A COLONY AT ONE TIME.

ABOUT two years ago, if I am not mistaken, Prof. Cook gave a method of preventing increase of colonies by swarming. Briefly, the plan was to remove all queen-cells and two frames of brood from the colony that cast the last swarm, and then hive the new swarm in that colony. I have tried that plan for three years, having practiced it one year before the publication of Prof. Cook's article. Generally the plan has been very successful; but in one respect it has proven a failure. To prevent misunderstanding I will give my plan in full. After warm weather began, so that the bees could fly, I began feeding to stimulate brood-rearing, so as to have early swarms, and most colonies swarmed in fruit-bloom. Probably all would if I had not put more frames in some of the hives, giving the bees more room.

When they began swarming I would remove all queen-cells from the hive that cast the last swarm, take out two frames of brood, and give to some nucleus, replacing them with empty combs, and put the next swarm in that hive. If I had not put on any crates I did so at once. If a crate was on the hive I put on another. My queens are all clipped. As for swarms coming out in fruit-bloom, the plan was a success. No fighting, no afterswarms; the queens were all accepted at once. About once a week I looked through for queen-cells, but seldom found any. But after white clover was in bloom, the old stock and the swarm would go to fighting unless I smoked them thoroughly, and the queen was killed in every instance. This has been my experience for three years. Not a queen has been killed before the bees began to work on white clover. Every one has been killed after white clover began. I should like to ask if any others have had like experience.

On the 17th of May a colony cast a swarm. I caged the queen, moved the hive around, and put a new hive on the old stand. When about half the swarm had entered, another colony cast a swarm—a second swarm, as I had purposely left the queen-cells in. This swarm at once began to enter the hive with the other. I caught the queen, and let the two go together. I gave them a frame of brood with eggs, and did not look at them for more than two weeks. Then on opening the hive I found 12 queen-cells, 7 of them open. On further search I found three young queens on the frame. Of course, I thought the queen was dead; but, to my surprise, on the third frame I found the old queen and a young queen on the same side of the comb, and another on the other side. On the next frame were the other two. The next day I found two more queens, and the next day another, which had hatched the previous day—ten live young queens in one hive! Can you equal that? The colony from which the larger swarm came last year, I "unqueened," and they sealed 36 queen-cells on one frame. The colony cast a swarm, and that is the one that cast the second swarm. I unqueened them this spring, and they built and sealed 29 queen-cells; so queen-raising would seem to be hereditary in that colony.

As so much is said on folding sections, let me give my way. Take a board about 12 inches long, 6 wide, and one thick. Cut off one end perfectly square; nail on a piece of board about five inches wide and as long, so that it shall make an exact right angle, and be exactly as high as a section; 4¼ inches from this, nail a cleat on the bottom board. Bend the section in the middle, and put the corner thus formed against the cleat; press the sections into the angle formed by the upright; now bend the top down, and one blow of the mallet will finish the section. After a few minutes' practice, the section can be pressed into the form, ready for the finishing tap, as quickly as it can ordinarily be bent together, and it is hardly possible to bend one out of true.

S. J. BALDWIN.

Nelson, Ohio, June 25, 1886.

Friend B., you have got a queen that seems willing to permit young queens to be reared in the colony without molestation. Such queens are found in almost every apiary, every little while, and they are very valuable for queen-rearing, inasmuch as we can rear queens right along and still have a queen constantly keeping the hive populous. Such queens would be as great an acquisition to the bee-keeper as non-sitting hens are to the poultry-raiser. The matter has at different times been pretty thoroughly discussed in our back volumes. By all means, save every one of those queens, and see if you can't get a strain of bees that will allow several queens in a hive all at the same time. A race of queens that won't quarrel! just think of it, friends! what an acquisition it would be! and I feel just as certain that it can be managed as that we can get a strain of kohlrabi-seed or cauliflower-seed that will give plants true to name every time. Prof. Cook has for a good many years scolded because we don't try to improve our queens, instead of trying to produce them so cheaply. Why can we not do for bees just what the world is doing for small fruits, garden vegetables, and the like?

QUEEN-EXCLUDING HONEY-BOARDS.

CARNIOLAN BEES, ETC.

THE value of perforated zinc in honey-boards, I have this season established to my full satisfaction. The question had been, Is it not an obstruction to the work of bees in supers? I can now answer that it is not. Its introduction to bee-keepers has made possible several new inventions in hives that, without it, would be quite impracticable. By its use, surplus-receptacles can be placed over very shallow brood-chambers with success; and, if desirable, we can take in marketable shape almost every drop of honey a colony can produce. In the spring we can build up colonies, and enlarge the brood-nest to the full capacity of the queen; and then at the right time we can limit her work and prevent the rearing of non-producing workers to any desirable extent.

The feature of greatest merit in the new Heddon hive is the horizontally separable brood-chamber; and my experiments so far this season have proved that it is worthy of all the praise that has been bestowed upon it. But, as predicted in GLEANINGS for March 15, it is impracticable to use such a hive on the contraction plan in the production of comb honey without a queen-excluding honey-board. Three years since, I found that it was impracticable to contract brood chambers to any great extent without limiting the queen, and then I made my first wooden queen-excluding rack, and at the same time tacked narrow strips of perforated zinc on a slatted honey-board. The latter worked very nicely, and, in fact, the wooden one did very well, as also a rack prepared with long strips of tin; but the metal could not be held properly with brads, and so last season I conceived the idea of making saw-cuts in the edges of the slats with a thin circular saw, and inserting the zinc in them. This plan of using the zinc, I found to work perfectly; and I believe that I was the first to conceive the idea, as well as to construct a honey-board of this kind. Certainly I was the first to make it public, and think I am fully entitled to give the invention to the public as I have done. After testing the invention I sent a hive to the Michigan State Fair, having such honey-boards, and it is just possible that my friends there who claim to have been original in conceiving such use of the zinc had there seen my invention and forgotten about it. I believe, however, that these friends do not claim to have constructed such a honey-board before this time—only to have conceived the idea.

After a number of trials I found that the strips of zinc work the best when cut wide enough to make three rows of perforations. The slats were made nearly as wide as the strips of zinc. My new hives have all been made *narrow*, to hold only 7 brood-frames in each case, so that the honey-board is only 10⅝ inches wide. It is essentially the new Heddon honey-board, made substantially as friend Hutchinson describes on page 527. As I now construct it, it has 4 of the strips of zinc, giving 12 rows of the perforations for the bees to pass through; but in the honey-board, made with 7 slats to correspond with the frames, I could get only 8 strips of the zinc in, making only 8 rows of the perforations.

In the *C. B. J.* for June 23, this honey-board is illustrated; but if made as there described, part of the perforations will be useless, from the zinc sinking too deep into the saw-cuts. Again, the use of the cross-bar in the middle is unnecessary, as there is sufficient rigidity of the board without it; and I make the slats only 5-32 of an inch thick. In cutting up the sheets of zinc we cut out every fourth row of the perforations, leaving the solid strips of zinc whole. In making this new honey-board I have used friend Root's new perforated zinc with success, and am able to recommend it to bee-keepers as perfectly adapted to the purpose designed.

THE CARNIOLANS.

Dr. Morrison inquires about the quality of the workers of the queens he sent me last fall. She proved to have mated with a Syrian drone, as he had anticipated; and the workers, though well-marked hybrids, were fully as gentle as Italians. The queen was very prolific, and filled the equivalent of eleven L. frames with brood, and then led a swarm June 9th. Sections had been adjusted, and a start in them made. The swarm was very large. After filling a space equal to 8 L. frames they began in the supers, and have made to date, in black-walnut sections, 40 lbs., and the parent colony as much more, and they will raise the amount to 100 lbs. They reared about 50 queen-cells and an innumerable quantity of drones, although they had not much drone-comb. All were jet black; and as I did not wish them to cross with my white queens I opened the hive and destroyed them. The comb honey produced was capped very white, but not whiter than that made by my own strain, some colonies of which have already made 125 lbs., and will probably reach 150, which I consider a large yield for an exclusively white-clover district.

The queen obtained from GLEANINGS office at the same time as Dr. Morrison's, was striped and very pretty. Her workers appeared like Italians, with an occasional black bee. The drones were also like Italians, with some quite dark. This queen also led a swarm about a week later, was very prolific, and left 48 queen-cells. Both colonies were in the new Heddon hive, and every one of the queen-cells was built from the edges of the bottom-bars, so that, on separating the hive, we found them all sticking straight out, ready to be cut off. It beats the Alley plan of getting queen-cells, all hollow.

The swarm having friend Root's queen has made only 20 pounds of surplus, and the old colony nothing, although all the frames were reversed, and the brood raised against the sections. These bees are evidently not fair representatives of the Carniolans; but Dr. Morrison's are good workers, and I have reason to think the Carniolans are generally. It has been alleged, that they are given to much swarming, but I doubt it. The yellow specimens of the race that now and then crop out should be destroyed. Especially ought all yellow-marked drones to be destroyed by the breeders of these bees, and the race kept pure. DR. G. L. TINKER.

New Philadelphia, O., July 8, 1886.

We are much obliged for your candid and impartial opinion of the Carniolans. However, as Dr. Morrison's queen was crossed with a Syrian drone we can hardly determine whether the results would have been equally good had the progeny of the queen been pure Carniolans. We are glad to note that the crosses of the Carniolans are not cross. As your experience with the strain of Carniolans which we have in our apiary coincides with our experience, we think we were right in saying that they were inferior workers. We are glad to hear that the strain Dr. Morrison keeps has done much better.

Please accept our thanks, doctor, for the beautiful workmanship on your queen-excluding honey-board sent us. We may have an engraving of it made. These honey-boards, made partly of wood and partly of zinc, promise to be an important implement in the apiary; and since the subject is up, we give below an article from friend Heddon, which we extract from the *Canadian Bee Journal* of July 7. Dr. Tinker already alludes to the cut of a honey-board, given in the *C. B. J.* for June 23. It seems that many minds are working on this very thing; and although the different experimenters have different ideas, as usual, we think we shall ultimately come along to what is pretty nearly common ground. Below is the article from friend Heddon:

HONEY-BOARDS.

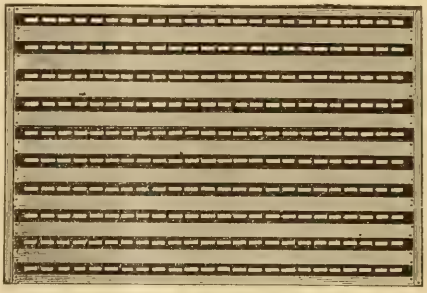
Referring to your "Own Apiary," page 245, where you illustrate a queen-excluding honey-board of combined wood and metal surface, I will say that we are experimenting on an extensive scale with these boards, the idea of metal strips being let into grooves in the sides of our honey-board slats having originated with at least four different persons a year or more ago. I may name Dr. G. L. Tinker, who wrote about it not long since; C. E. Boyer, my foreman; W. Z. Hutchinson and myself, neither being aware of the other's device, and all giving it to the public. Here we are using it as follows: We make our wood slats the same width and thickness as ever, leaving the spaces between them the same three-eighths inch, and slide in metal strips having one row of openings only, and these strips we get made to order, with their edges all smooth and whole, and I can not see how smooth edges are secured by cutting strips containing "two rows" of openings, any more than a strip of only one row, which leaves the jagged edges, which work just as well in the boards, but are more trouble to insert. My experience and observation with bees fully convinces me that one row of openings over the center of each top-bar, below will give far more than ample passage room for the strongest colonies. I will tell you why I object to using metal strips wide enough to contain two rows of openings: It necessitates, as in friend Hall's case, five-eighths space between the slats. Now, if the bee-space is right between the surfaces of the slats and the surfaces above and below them, of course it is about one-eighth of an inch larger between the surfaces of this metal and the surfaces above and below it. I think we should be more apt to be troubled with brace-combs where we used two rows of openings, than where we used one, as I have it. I am not sure but quarter-inch between the slats would be better than our three-eighths. I can tell at the close of this season. I have used brood-frames with top-bars three-eighths inch thick, and varying in width from thirteen-sixteenths up to one and one-eighth inch, and I have found brace-combs built between their *edges* to a greater extent in proportion as the bars were wider and the spaces narrower; but this kind of bracing is between the edges of the bars, and not between their surfaces and other surfaces above and below them. In testing some thirty all-wood queen-excluding honey-boards, made so by widening our quarter-inch slats till the spaces between them were the same as metal openings, in width, we were astonished to find that the bees built comb in these spaces till two thirds of the passageway was stopped. We tried them two seasons, realizing this and other disastrous results, and have discarded them entirely.

HEDDON'S HONEY-BOARD.

"What is it?" I receive many questions like this. Will you kindly let me reply to many at once? An implement, machine, or manufacture, may take its name from him who constructed, devised, or invented it. A device may or may not be an invention; and it is a question as to whether placing these strips of metal in grooves in the slots can be called an invention or not; but whether it is or is not, it is certainly a device, and preferable to nailing it on to one side as before. My honey-board contains two important features, each of which performs very useful functions, and which I invented some eight or ten years ago. 1. Arranging slats within a frame or rim, in such manner that one of their surfaces shall be even with one surface of the rim, while their other surface shall be a bee-space lower than the other surface of said rim. This gives us a honey-board containing a bee-space within itself. The rim gives it solidity, when the slats are made as thin as quarter-inch, as we make them. 2. Arranging slats, forming a honey-board, in such manner that the center of each slat shall run parallel with, and rest directly over, the space between two brood-frames below, and the center of the top-bars below shall come directly under the spaces between the said slats. Any honey-board that contains neither of these principles is not a Heddon honey-board; but one that does contain either of them is. Extensive and repeated experience with these boards not only gives me the knowledge that their usefulness by far outweighs their cost and manipulation, but they are in no way whatever any detriment or hindrance to the bees and their work. You will notice that, by fitting your hives and supers to a honey-board containing a bee-space, the same can be used without the honey-board, all bee-spaces remaining as perfect as when used in connection with it. This honey-board has never been patented, except in combination with my new hive, as described in past numbers of this journal. It is used and highly prized by such producers as Dr. C. C. Miller, R. L. Taylor, W. Z. Hutchinson, Prof. A. J. Cook, and scores of other equally expert bee-keepers, less known to the public. I am confident that it has come among us to stay. JAMES HEDDON.

Dowagiac, Mich.

Below we give an engraving of a honey-board made on Heddon's plan, fitting the Simplicity hive.



QUEEN-EXCLUDING HONEY-BOARD, ARRANGED SO AS TO HAVE THE OPENINGS JUST OVER THE TOP-BARS OF THE BROOD-FRAMES.

The engraving shows the honey-board with the smooth or level side uppermost. The wooden slats are 1 inch wide, and a little less than ¼ inch thick. The spaces between them are ⅜ inch. The end-pieces to which the ends of the slats are nailed were originally ⅞ x 9-16. A rabbet is made in one corner of this strip, ¼ x ⅜. For use on the Simplicity hive there is no frame clear around the honey-board, as Heddon has them; that is, the honey-board is composed of simply the end-pieces and the slats. It is put on the hive with the bee-space downward; and as our crates are all made with bee-spaces under the sections, when the case is set directly on the honey-board it comes all right. The price of these honey-boards is 25 cents each; $2.00 for 10, or $18.00 per 100. If wanted by mail, add 22 cents additional for postage.

CARNIOLAN BEES GREAT WORKERS.

ARE THEY A PURE RACE?

JUNE 3d I put a swarm of Carniolan bees into a two-story Simplicity hive with 20 frames filled with wired Van Deusen foundation. In eight days after that I extracted, from the upper story, 40 lbs. of white-clover honey, and left the lower ten frames filled with honey. On the 17th of June I extracted, from the same combs, 38 lbs. more; and then to see if Carniolans would get tired of drawing out foundation I gave them ten frames again, filled with Van Deusen flat-bottom foundation. Yesterday, July 8, I extracted 50 lbs., capped, as white as snow, from these same frames of foundation, and the ten combs below are still full of brood and honey.

THAT QUEEN OF ILA MICHENER'S NOT PURE CARNIOLAN.

Your publication of Ila Michener's letter gives me a right to a reply. I do not believe he has a Carniolan queen, and some time since I wrote him to this effect. I may have made a mistake, and sent him a hybrid Italian last year. If I did, it was not the result of any less care in breeding queens than is exercised by the most careful. As an instance of how such a mistake may occur: A few weeks since, I put an after-swarm into a nucleus hive with foundation and one frame of brood. Two days after, I removed the virgin queen, intending to give a Carniolan virgin the next day; but the next day, on examining the colony I found another virgin queen. Now, suppose I had run my Carniolan queen into that nucleus without knowing that other queen was there, wouldn't I have sent that other queen to Ila Michener or somebody else in ten days? This is but one instance of how a mistake *may* be made. I know of others, and am convinced that, with all the care the most careful breeder may give the business, errors will happen. Probably less likely, but yet possible, the receiver of a good queen may lose her and not know it. For instance, I removed, a few weeks since, a queen from a strong colony, where I had placed her some days previously, to a nucleus hive in a distant part of the yard. Three days after, I found a laying queen in this same hive. There is positively no mistake as to these statements. Now, suppose I had smoked this colony and given them a queen on the third day, not having found the other queen, accidentally, and on the fourth day "found her laying," wouldn't it have been another queen? and wouldn't I have sent a complaint to GLEANINGS that somebody had imposed on me? I have seen a great many other methods through which mistakes may happen on the part of the breeder or the buyer of queens, for I do the whole of the work in my apiary; and keeping a written record on each hive I have often seen these anomalies.

Some time before seeing Ila Michener's letter in GLEANINGS I wrote him in substance as above, and offered to send him another queen, but have had no reply. My offer still holds good to him, for he is doubtless one of our "square" men.

"If they are not a pure breed, would it not be best to drop them right where they are?" This is your question on page 548. Now turn to page 527 and read from W. Z. Hutchinson about the "Swarming-out Mania" of Italians — real Italians, and not hybrid Carniolans (to say the best we can for Ila Michener's); then read what Mr. Robbins says about his inability to prevent excessive swarming, on p. 540; then the "Swarming Mania Raging," by John Nebel & Son. If this is the trouble Italians are going to give us, would it not be best to drop them just here? Oh, no! I am satisfied that my Carniolans are fully equal to Italians as workers; and that, either purely fertilized or fertilized with Italian drones, their workers are much gentler and pleasanter to work with than Italians, and these are the qualities I want. I don't give much for the dress or adornments of bees.

"ARE CARNIOLANS A PURE RACE?"

I can't tell. Ask Mr. Benton or some other reliable person on the ground. He says Italians are not a pure race, and that settles that question. I can only say that my imported Carniolan queen produces no progeny with yellow bands; but they are of a uniformly steel-gray color.

GETTING BEES TO WORK IN SECTIONS.

GLEANINGS for July 1 contained the most directions I know any thing of. If I want increase of bees I give all the comb and foundation in the brood-frames I can get. If I want work in sections I put into the brood chamber — one on each side — two wide frames filled with sections full of comb or foundation, and, between these, seven frames with an inch starter of foundation, and set on top of the hive a combined shipping and honey-crate (I never use these for shipping honey) also filled with sections full of foundation. I am never more certain of honey in sections than when a swarm of bees is put into a hive arranged as above.

S. W. MORRISON, M. D.

Oxford, Chester Co., Pa., July 8, 1886.

We are very glad to get so good a report from the Carniolans, especially as our experience with them has been rather discouraging. It would seem that you have a better strain of these bees, friend Morrison (see in the article above, what Dr. Tinker says of the comparative working qualities of *our* strain of Carniolans and yours). We often notice the same difference between different strains of Italians; and it would be nothing strange if Carniolans were like them. Before the clover bloom, and before the imported Carniolan colony had cells started, or had any thoughts of swarming, they were more than once on the eve of starvation, while the Italians were supporting themselves easily. Even when the honey-flow commenced, although the Carniolans were making no preparations to swarm they did not begin to fill the combs in their brood-chamber, though it was a large colony. When the statement was made, that they were poor workers, it was done because we felt it our duty to do so, even at the risk of spoiling our own trade in untested Carniolan queens. We have not, and do not now claim, that, because *our* Carniolans were inferior workers, therefore *all* are. Indeed, Dr. Morrison (whose statement we have no reason to doubt) has a strain of these bees that are good workers. If any are desirous of securing a Carniolan queen, we would with pleasure recommend them to him. In favor of the Carniolans so far as we have observed, we will say this : They are very quiet, easy to handle, adhere to the combs, are good breeders, little inclined to propolize, and are, perhaps, a trifle larger than the average Italians. In disposition they are quite different from blacks ; but nevertheless in *appearance* they very much resemble them. In fact, it seems that Dr. Morrison himself does not always distinguish the difference, or he would not have made the mistake in sending a *hybrid* queen to Ila Michener, when he intended to send a *Carniolan.*

ERNEST.

ARE DRONES FROM A PURE MISMATED QUEEN PURE ?

SOME VALUABLE FACTS FROM FRIEND SWINSON.

FRIEND ROOT:—On page 545, in your foot-notes, replying to F. Clare, as to hybrid bees, you state that drones from a pure Italian queen, which has mated with a black drone, will be pure Italian drones, which, then, would be just as good as drones from an imported Italian or any other Italian queen. I have read this same thing repeatedly, from different parties for the past four years; but I found, on trial, that it won't work according to theory, worth a cent. Why, friend Root, if this were so there is no need of a man having 25 or 30 colonies to Italianize to buy more than two pure Italian queens to do it.

In 1884 I had 20 to 29 colonies of blacks, except 3 pure Italians. In May I killed all the black queens, and reared in each hive an Italian queen; these, of course, were nearly all mated with black drones. In August and September, after all the black drones were gone, and nothing left in the apiary except pure Italians and drones from these pure mismated queens, I again removed all the hybrid queens, giving cells bred from the pure stocks, as before. Now, when the progeny of these queens hatched out they should have been pure, according to this theory; but, not so; they were nearly every one hybrids, as in the spring trial, except that none of the progeny were full black bees, as in the first cross, but they were from one to three mingled-banded bees, such as hybrids always show more or less of. They were exactly what C. Kingsley sent me last spring as tested Italian bees—nothing but hybrids, yet pure, according to the theory. I continued to breed up queens, and have them mated to these drones as late as I could; and, not being able to produce pure Italians in that way, I sent off and bought 20 odd queens of S. D. McLean, of Tennessee, and introduced them in place of these queens mated with drones that were bred of pure queens mismated.

TO START BEES TO WORK IN SECTIONS,

Or any part of a hive you want them to go to work in, is a very simple thing to do, if they are working anywhere. This is the way: Take a piece of comb having sealed and unsealed brood in it, and place in one of the sections which you want them to occupy—box or any other contrivance you want honey stored in, and they will certainly go to work around it; they won't desert brood and larvæ as they do honey placed up in sections to start them; and as soon as they get well started and under way you can remove the piece containing brood. This is a never-failing remedy; it will start the most obstinate colonies, and is very simple and easy of trial.

CARNIOLANS.

They do show bees having two yellow bands, and even an occasional one with three; but they are a smaller and more reddish-looking bee—rather dwarfish-looking fellows compared with the regular Carniolan workers; so, at least, do the Carniolans I got, and they, too, are from imported mothers, two of which were sent me by Mr. Benton in August and October last, as first-grade queens. They are very gentle indeed—good workers, but they make little show for it in their hives, in the way of surplus, as they are such excessive breeders that they use more than most bees do in breeding. This is the only reason I can give to account for their lack of stores, as they certainly do work well. They just teem with fertile workers, if made queenless for six or seven days. They have plenty of fertile workers in their hives, even when having a queen hatched in it several days old. They beat Henderson's Syrians for fertile workers. 4—A. L. Swinson, 71—72.

Goldsboro, N. C., July 5, 1886.

Friend S., I do not see that you demonstrate at all that the drones from pure Italian queens, when crossed with a black or hybrid, are *not* pure Italian. The theory was first propounded by Dzierzon, and then verified by that careful experimenter the Baron of Berlepsch; and, if I am correct, it has not been proven untrue as yet. Your experiment upon the point in question is faulty, in that there might have been, and probably were, black bees within your immediate vicinity. Besides, it seems to me you could not prove there *were* no black bees near you. At the bottom of your letter I see you have been in the business for four years; so at that time (1884) you could hardly have Italianized the wild bees in your vicinity.—The plan you mention, of inducing bees to go into sections, is the same as that mentioned recently by Doolittle.—Your experience with the Carniolans is similar to ours, that they make little show of honey in the hives. Ours, however, do not even seem to work well. If Carniolans teem with fertile workers when queenless, it certainly is a bad trait. As we have raised no queens from our Carniolans, we have not tested them in this particular. I would recommend you, friend S., and all others who feel undecided about the drones from pure mothers, to go over again our little book called the "Dzierzon Theory." It is mailed on receipt of 12 cents.

CARNIOLAN BEES, AND ARE THEY GOOD WORKERS?

FRIEND J. B. MASON TELLS HIS EXPERIENCE WITH THEM.

In Gleanings for June 15, Ernest strikes a blow at the Carniolan bees, pronouncing the verdict upon them as worthless, as he says they are poor honey-gatherers, and concludes by warning the friends about investing in them. This seems hardly fair to pronounce judgment on this race of bees in that way, until you had tested them further than one or two queens, especially as I believe Mr. Benton held that there must be some mistake about one of them. Had I judged the Italian race of bees by the three first queens I ever had, or from two that I bought later on from a very prominent breeder, I fear I should most surely have condemned the race, for they were as near worthless as Ernest describes the Carniolans. They were not self-supporting; and from the reports of others I at once decided that there were better Italian bees than I had got; and after procuring some from another strain I found a vast difference in them.

For two years past I have been testing the Carniolans, and I must say I have found them superior in all respects to the Italians for comb honey. My Carniolans do not show yellow bands, as Ernest speaks of, and they have no lazy or sluggish actions, but are among the very best workers I have ever seen. They are certainly better comb-builders than any Italians I have ever had, and build whiter combs, and take to the boxes more readily; and as for gentleness, they are gentler than any I have had. If one wishes for nothing but extracted honey, perhaps there may be none better than the Italian bees.

It is evident to my mind, that these so-called Carniolans that have bands are hybrids. You may say they were imported. Well, the next thing is, are there no hybrids where they were reared? I received two imported Italians from a dealer whom I think you would pronounce perfectly honest; but I pronounced them both hybrids, and I will bet a trifle they were. A. I. Root pronounced them so, as I sent a sample of the bees.

In July 1st Gleanings, Ila Michener speaks of procuring a queen of S. W. Morrison, and he says she was a hybrid, temper not excepted. Well, now I should ask, Did not S. W. Morrison sell her for a hybrid or an untested queen? Mr. Michener asks if we are not being imposed upon, and getting back our old bees again. I answer, no; the characteristics of the Carniolans differ as much from the German bees as do the Italians. I think Mr. Michener has no need to regret that any of the Carniolan blood has been introduced into his apiary, provided comb honey is his object. I believe, friend Root, if you hold your judgment on these bees until you have tested them further, and until you get the reports of those who are now testing them you will have good reason to change your views on them. Will you please allow me to send you a Carniolan queen to test, and give a report what you think of her? J. B. MASON.

Mechanic Falls, Me., July, 1886.

You are right, friend Mason. It is hardly to be expected that the workers from two queens would be a fair test of the race in general; but if you will turn back to the article to which you refer you will see that it is so stated. Perhaps we were a little hasty in drawing deductions; at any rate, see what Abbott L. Swinson says of them. We are ready for reports now from others; and as it is hard to tell definitely from the worker-bees raised from the daughters of the imported Carniolans, I should like to have reports from the worker-bees from the *imported* Carniolan queens themselves.

THE FIRM OF JANE MEEK & BROTHER.

A Serial Story in Ten Chapters.

BY EV. W. D. RALSTON.

CHAPTER VIII.

BRIGHTENING PROSPECTS.

TOMMY thought over their debt day after day. It worried him. He knew, from talking with his father, that they should need at least seven new hives and ten pounds of foundation for another season. This would likely increase their debt to thirty-six dollars, before they would have any honey to sell. In the wood-shed was a carpenter's bench and a number of tools, for Mr. Meek liked to work with lumber. He also allowed his children to use his tools, and had often instructed them in the use of these tools.

One dav Tommy had been at work making a rabbit-trap, and had just finished it when Jane came in after some wood. She looked at the trap, and admired it very much, and then asked, "Why could you not make our *hives?*"

Tommy said, "I believe I could, if father would let me use that planed lumber that is upon the joists."

When they asked their father, he said, "If you make hives that will answer, you can use the lumber, free of cost, and I will also furnish you nails; but if you merely waste my lumber and nails, or make some old rattle-box of a thing, and call it a hive, I will charge you for both."

Said Tommy, "I will be careful, and do the very best I can."

Mr. Meek then told Tommy and Jane to bring the empty hive into the wood-shed. He went there, measured its different parts, and sawed out one piece of each. These he directed Tommy to mark, and use as patterns; and Tommy found them a great help.

For some days Tommy and Jane worked carefully at the hive, and at length the first one was finished, and their father was asked to examine it. He said it would do, but showed Tommy where he had made some mistakes, and also where it might be improved. As Tommy always attended school, when in session, the seven hives were not all made and painted until May. One day, when the children were from home, Mr. and Mrs. Meek were in their storeroom looking at their hives, and Mr. Meek said to his wife, "If those children never sell a pound of honey, what they are learning by engaging in this work will more than pay all expenses."

As the lumber and nails were furnised by Mr. Meek, the seven hives cost only $1.50, for oil and paint.

The four colonies were wintered in the cellar, and placed in the yard the following spring.

The one in which was the new queen was found badly diseased. It had dysentery, and the hive was in a filthy condition. After the bees had a flight, the combs were removed by Mr. Meek to another hive, and then warmly covered with cloths. It finally rallied, and, by exchanging an empty comb for one of sealed brood from one of the other hives, it became strong by the time white clover bloomed.

That winter there had been much snow covering the ground, and protecting the clover; and in the following summer there was a most bountiful bloom of white clover. The children, under their father's directions, had prepared cases of nice clean sections, ready to be placed on the hives. They had also prepared their frames for the lower story of the new hives by fastening strips of foundation two inches wide along the top-bars. They did this to encourage the bees to build straight combs. Long before the time came for placing the sections on the hives, they had all things ready; or, as Mr. Meek expressed it, their dish was "turned up to catch the honey."

When they saw the white clover beginning to blossom, sections for surplus were placed on the hives. When these became filled they were elevated, and others put under them; and in this way the bees were kept busy, and no sections were removed until every cell was sealed.

When swarms issued they were hived in nice new hives, with wide starters of foundation in every frame, and in a short time they had filled their hives with nice straight combs, and had begun work in the sections, a case of which had been placed on all first swarms a few days after hiving.

As abundant room for the storage of honey was always afforded, and as the hives not shaded by the trees and shrubbery were well protected from the sun by boards leaned up against them, there was not much of a disposition to swarm. It seemed that the honey so abounded in the white clover, and they were so busy gathering it, that they forgot all about swarming.

They had only five swarms, so when the season closed, the firm possessed nine colonies; but the pantry shelves were groaning under the load of nice comb honey that had been placed on them. There was not much basswood in reach of their apiary, therefore this honey was mostly from white clover.

After the clover-yield, all the hives, by Mr. Meek's directions, were reduced to one case of sections, to await the yield from fall flowers; but for some reason there was no honey gathered from that source. When these cases were removed they were found empty. Although many sections were partly filled with light honey, when the flow from that ceased, all were found to be empty, the honey having been carried below; but an examination showed that the hives were heavy, and that doubtless all had abundant stores for winter. They found honey in the fall flowers, but not enough to send them into the sections.

The crop of honey was 447 pounds, every section nicely filled and sealed, and as white as snow. After selecting 72 pounds of the nicest sections for home use, the rest was sold to a grocer in the town at 15 cents a pound. When the firm delivered this honey, and received $56.25, they felt rich indeed. That night they posted up their books for the year. They found that their entire outlay had been only $6.75, which, added to the $20.10 owed their father for last year, made $26.85 as their entire debt. This they paid and had $29.40 remaining. They were now out of debt, and could feel that their apiary was all their own, and the question was, what to do with the rest of their money. Their mother advised them to place it in their father's keeping, and use it as needed to provide supplies for their apiary. Their father said that as they had three empty hives, he thought ten new ones would be abundantly sufficient to hold next year's swarms; that he had no lumber on hand, and that, if Tommy made hives, he would have to buy lumber, and that it would be better to order hives in the flat from the supply-dealer. These would be planed, and cut out all ready to nail, and would cost only a little more than the lumber. Ten hives would cost 85 cents each; so the money was sent for them. They also ordered 1000 sections.

Mr. Meek wanted Tommy to study diligently; and he well knew if ten hives had to be made by him it would interfere with his studies; therefore he advised buying hives ready to nail. To nail and paint these was a comparatively short job, and it was all done before school opened.

One evening, late in the fall, Mr. Meek returned from a short journey he had taken in his buggy. The children ran out to greet him, when he lifted a large tin can from his buggy, and asked if they knew what it was. After they had examined it Tommy guessed it was a churn; and Jane said it was a machine for making apple-butter.

At length he told them it was a honey-extractor. They had read about that machine, and its use, but had never before seen one. This excited them, and they were for running with the news to mother, when their father called them back to care for the horse, as he was chilled after his long ride. When they returned from the barn they carried the extractor with them into the house. Their father, now warm and comfortable, explained that, where he had stopped the previous night, the farmer had at one time owned quite an apiary; but an invalid son who cared for the bees had died; and as there was no one to take his place, the bees had been neglected, and finally all had died. He was selling his hives and fixtures, and had offered this extractor and uncapping-knife for three dollars. As it was not half its cost, he bought it for the firm. He then showed the children how to take a frame of sealed honey, cut off the caps with the honey-knife, and place it in the revolving frame, close by the wire netting; prepare another frame of honey, and place it on the opposite side; then turn the crank rapidly, and the honey would be thrown out, and, striking the side of the can, would run down, and could be drawn off through the honey-gate. The combs would then need to be lifted out and turned, when the other side could be extracted in a similar manner. The combs, then free from honey, could be returned to the hive, and, in the time of a good honey-flow, would soon be refilled.

He said he felt confident that more honey could be raised by extracting, but it did not meet as ready sale in most communities as the comb, and sold at a lower price. To raise extracted honey, we need to prepare our hives with two sets of frames—one below for brood, and one above for surplus. A hive so prepared is called a two-story hive. The frames in the upper story are the ones extracted.

During the winter, Tommy, under his father's direction, made upper stories for two of their hives, intending to use those two for raising extracted honey.

To be continued.

SOME EXPERIMENTS WITH CANDIED HONEY.

IS THERE ANY WAY TO PREVENT ITS GRANULATION?

ONE man writes you that, if honey is kept in a warm room, it will not candy; another says, Seal it up hot; another, Keep it in the dark. Writers seem to ignore the fact that a test made with only one kind of honey is of no value whatever.

I noticed some months ago you spoke of honey not candying, even with a zero freeze. Are you sure that a zero freeze will cause honey to granulate more quickly than the most moderate weather we have in January? I am not sure that you are not right. My experiment which I am about to give is not worth much, for the reason that it was made with only one kind of honey. You will remember the year we had a drive together, some ten years ago. The following winter I took some of your Medina Co. honey (linden, candied solid). When we got it I melted it thoroughly, put up 10 half-pint glasses, placed two in the office where there was a self-feeding hard-coal stove, perfectly warm—I should think certainly above 60° the 24 hours—two in the yard exposed to a zero freeze; two in the cellar, wrapped up in dark paper placed in a dark room; two in the hallway where it would be about the freezing-point all the time, and two in the wareroom, where it was warm in the daytime and cold at night. Now, inside of two weeks every glass was candied solid, and I could not distinguish any difference in the time that it took for each one to become candied.

That same season I went to the Shenandoah Valley, in Virginia, and bought some honey from the blue thistle, in the comb. The following May that honey was not candied. After I left there, which was in August, they had a good yield from a yellow flower, I think the goldenrod. Some of that was sent to us; and although that was taken out of the hive after what I have already spoken of, it was candied solid in the combs in the month of November.

When a man tells me how to keep a certain kind of honey from candying, then I am ready to listen to him; but when he tells me how to keep *honey* from candying, then I know that he does not know what he is talking about. I don't believe there is a possibility of keeping your linden honey from candying, and dozens of other kinds are just as liable to candy. Now, my experience has simply taught me that, if I go and buy one kind of honey it will candy quickly; and if I buy another kind it will remain much longer in the liquid state; but as for preventing the granulation in the winter season, I am as ignorant as the day I was born. I have also learned that honey placed in a glass, with a small piece of candied honey put in it will granulate in the month of July, the candied portion working like leaven, until the whole glass is in the same condition.

Some one in GLEANINGS lately made the statement, that when honey granulated shows grains, it is an evidence of purity; and that when it is smooth it is an evidence of adulteration. Now, I think he is mistaken. I go to a commission house to buy California extracted. I open one can, and find it is grained nicely—that is all I want to see. I don't need to taste it—it will suit me. I open another can in the same lot in the original package, and I have no doubt of its purity. I find it is candied, but smooth; a little darker than lard, but otherwise exactly like it in the smoothness of its appearance. I don't want it; the flavor is not good; yet I have no doubt of the *purity* of the honey. You bee-keepers laugh at people's ignorance when they say they don't want candied honey; but that does not help the matter. You and I have not a sufficient lease of life to hope to see the day when the masses in our cities will be educated to buy honey in the candied state; and it is the masses in our manufacturing cities who must be depended on to use up the great yields of honey which seem to be increasing every year. What is the remedy then? I think it is the wisest course to recognize the existing prejudice against candied honey, and do the best you can to give them the honey in a shape that they will buy. It seems to me that it would be quite within the province of the bee-journal to experiment, and learn the kinds of honey that will remain the longest in a liquid condition; and the intelligent apiarist would then know that it would be to his advantage to market that which candies quickly in the comb, for we all know that honey, being slightly candied in the comb, will not interfere with its sale. It seems to me that, if no extracted honey were sold that was inferior in quality, or that would candy quickly, it would help the sale of honey wonderfully.

There is an evil in the business which I wish to speak of, and then I am done. It is the putting of two thick pieces of glass and a stout frame, all to hold one little piece of comb honey in its place. When I see a man give value for money, and at the same time prosper, I bid him Godspeed; but when a man owes his prosperity to his sharpness in being able to induce customers to buy two big pieces of glass, with the little piece of honey and all to be weighed as honey, I feel like asking him if he is running his apiary in full accord with the golden rule.

M. H. TWEED.

Allegheny, Pa., July 5, 1886.

Friend T., I have read your article carefully all the way through, to see if you touched on the plan laid down in the A B C book, of sealing up the honey while hot, to prevent candying. I have never had proof that this will not keep it perfectly limpid, providing the honey is sealed up exactly as we seal up fruit. Of course, it must not be heated to the boiling-point, as this will injure the honey. You speak of putting the honey in half-pint glasses, but you don't say whether they were hermetically sealed, and sealed up while hot. I am very well aware that there is a great difference in honey of different kinds. Some will never candy, and I gave up trying to make them candy. Horsemint honey, I believe, has never candied with us; and the pure white-sage honey of California—at least some specimens of it—we have kept year after year, winter and summer, without candying.—Now, I want to protest a little against what you say in your concluding paragraph. Putting up honey in the way you mention, and asking the same prices for it that you do for honey without the glass, might not be exactly the thing; still, if the purchaser wanted it in that way, I do not see why it would not be all right. Friend Doolittle has for years put his honey in glassed sections, and he has a class of customers who will not touch it in any other shape. Whether he still puts it up in this way or not, we can not say. We have had quite a quantity of this kind of honey; and when we first put it on our wagon, a good many took right hold of it, because it could be seen and handled without any danger of daubing. We sell it, glass and all, however, for 12 cts. per lb., while our nicest honey in light Simplicity sections brings 18 cts. per lb. When glassed comb honey brought from 25 to 30 cts., there was a chance to make money in selling it glass and all; but when it brings only 12 cts., I am not sure that the bee-keeper would come out very much ahead, after paying for his glass.

OUR BEES AND NEIGHBORS.

WHAT CAN WE DO TO PRESERVE PEACEFUL RELATIONS BETWEEN THE TWO?

FRIEND ROOT:—Please read the inclosed, and then consider the following: I should like it, or something better, printed in a neat, tasty form for *gratuitous distribution* among my neighbors. I should want only 300 or 400, but if you were to get up something to enlighten and mollify one's neighbors, I think you could sell them by the thousand, thus enabling you to print them cheaply. They might include some plain facts about bees, and a picture of the queen, worker, and drone. The people who are not bee-keepers are *very* ignorant, as a rule, about bees. Something about honey, and how to keep it, might be added. In short, if you think well of the plan, you can add or omit any thing you wish. I only send this as a sample of *about* what I want.

Now that I think of it, an item specially directed to storekeepers or grocers would be in place. They often complain. They leave sugar and molasses open to flies and dirt; and when the bees come around there is trouble. Town authorities sometimes know so little that they prohibit the bees. If you take kindly toward this, and will get up a neat, showy tract, or even one page, and send out a sample with GLEANINGS, I think you will have plenty of orders. One can't go around and tell everybody every thing. If it is printed in a local paper, it is forgotten. Besides, the local presses have not the experience nor facilities for getting out what we want. Please reply to this, telling me what you think of it, and what you will do, and what will be the probable cost per hundred of the "Tract of Useful Information to My Neighbors and Friends." A. CAMERON.

Derry Sta., Pa., July 10, 1886.

Friend Cameron, your suggestion is a most excellent one. I, like yourself, have labored to explain these things, and to set people right in the matter; but they have such erroneous ideas that it is a very difficult task indeed to tell the story all over to each separate individual. The greatest difficulty will be in getting people to read these tracts or circulars. But I think it quite likely that those who have been annoyed by bees will be quite ready to look into the matter, and with interest. Our readers will find the subject-matter of the tract alluded to below:

TO MY FRIENDS AND NEIGHBORS.

This is about bees. Please read it carefully and preserve it. The bees sometimes come into your house and annoy you. Perhaps you get stung, or they fall into your jelly-kettle, or sting the baby. I am very sorry for it all, and send you this little article, hoping to save you trouble hereafter. The bees try to steal only when the flowers are scarce. The worst time is in autumn, just when you want to make fruit butters and jellies; and to be worried by bees when you are tired and warm *is* provoking. Now, this is the way we do at our house, and we never have any trouble, even with the bees right in the yard.

1. Never set any scraps of honey or other sweets about the windows, or anywhere about the house, for the bees to *clean up*. They have good memories, and will prowl about for days, after having had a taste.

2. We never set jellies on the window to cool, unless we have a good wire screen at the windows. Most of the trouble is caused by exposing jelly in this way. The bees find it, and think it is theirs. A bee has no conscience, and will steal without remorse.

3. If a bee comes into your house, drive it out or kill it. Never let it get a load to carry home.

4. If they have gotten into your kitchen and into your jelly, you will have to be extraordinarily cautious for a week or more. Smoke is the best thing to drive them out. But they won't stay out, and you will simply have to shut up the house. But this will never be the case if you will observe the simple precautions above noted.

Permit me to say a word in defense of the bees. They are not an unmitigated nuisance.

1. By having a bee-keeper in your community you are furnished with a pure and wholesome food cheap.

2. Bees are useful, apart from the honey, in fertilizing the flowers of your fruit-trees and garden-vines. Without bees there would be no fruits, and your melon, squash, and cucumber vines would not bear. If you want me to explain this, I shall be happy to do so.

3. It is charged that the bees spoil grapes, pears, etc. They do suck the juice out of all broken fruit; but this would sour anyhow. They can't open the skin of a grape. The birds do the real mischief. I can prove this to your satisfaction, if you will bring a bunch of sound grapes, or any sound fruit, to my bee-yard.

4. People who live in towns must bear and forbear. The pigpen and privy are often nuisances across several lots. They should not be; but you draw a full breath some warm evening—whew! Besides, are you sure that our chickens are not often a mutual trouble, to say nothing of cats, dogs, and such like? And yet we manage, by forbearance, to get along neighborly, as is right.

I am sure that you will not do so wicked and useless a thing as to set out poison for the bees. If you have suffered any material injury, I will try to give you satisfaction. By setting poison for the bees, you not only do a damage to the bee-keeper out of all proportion to the harm his bees have done you, but you may cause the death of some person.

Any further advice or help in any matter relating to the bees, the undersigned will cheerfully furnish.

Derry Sta., Pa. A. CAMERON.

I want to add emphasis to your No. 3. If a bee comes into your house, and begins to sip up something sweet, the very kindest thing you can do to the bee and its owner is to kill it. If he slips away and gets back to the hive with even a small drop of something good, it is like a lighted match to a pile of shavings. It spreads, and very soon there is an uproar. Killing the bee is like blowing out the match before it has lighted any thing else. Some people think it is cruel and hard. A good many things are cruel and hard in this world, if we take a narrow view of them; but when one single insect, by his death, can save the lives of thousands, there should be no hesitation, and no weak, foolish sentimentalism. Kill him for the general good. The great troubles at the candy-stands and lemonade-stands on our fair-grounds can all be averted if the keepers of the stands will keep a paddle and kill every bee as soon as he comes around. I have seen this tried repeatedly.—In regard to the circulars, I think we will try our hand at getting them up. We will start them at 25 cts. per 100. If wanted by mail, 5 cts. extra for postage. I wish that others who are in the printing business may try it also. Let us see who can get up the most attractive tract for the smallest amount of money. A sample of ours mailed free to any one.

WHAT HAS BECOME OF FRIEND McGEE'S BEES?

DOUBLING FOR SWARMS TO PREVENT INCREASE, ETC.

FRIEND ROOT:—I send you herewith some basswood-leaves. You will notice that they are covered with lice, some with and some without wings. You will also notice that the leaves are covered on the upper side with a sticky substance, which was discovered first about the middle of June. The basswoods are covered with it, some more than others. I also find it on the hickory-trees. This is the first of this kind of stuff I have ever seen, and suppose it is the much-talked-of honey-dew.

The question with me now is, What has destroyed my bees? Is it this substance found on the leaves, or is it something else? On the 20th of May I had 24 strong colonies; from that date to the 15th of June all cast heavy swarms, and were hived as follows: 2d swarm where 1st had issued from; 3d where 2d had issued from, and so on, so that, by the 15th of June, I had gained but one colony. Of course, no after-swarming was allowed. You can imagine the strength of the colonies on the 15th of June. They were powerful. Up to that date they had done great work on fruit-bloom and white clover. Basswood opened about July 4th, and some trees are still in bloom; there is also an abundance of sweet clover, white clover, motherwort, and catnip, all of which the bees are working on. During the past week I expected a great deal of swarming and an immense crop of honey; but as something seemed to be wrong I went through all the colonies and found very few bees in the upper stories, and the brood-combs only nicely covered. They all looked as though they had cast a swarm the day before. The queens are the best, most of them hatched in 1885 and '86; their combs are filled with healthy brood, no dead bees in the hives, or on the ground in the apiary. Every thing seems to be all right except the absence of the field-bees. The new honey is of good color and quality; the capping is a shade darker than usual. Part of the colonies are working for comb and part for extracted; all are affected alike. What the outcome will be I can not predict, but I will report later. I can not believe that anybody is poisoning them, as I don't know that I have an enemy in the world.

I have sent Prof. Cook some of the basswood-leaves. GEO. H. MCGEE.

Point Marblehead, Ottawa Co., O., July 13, 1886.

Friend M., I hardly think the honey-dew on the basswood-leaves has any thing to do with the missing bees. It may be hard to tell what has become of them; but is it not possible they worked themselves out, wore out their wings, and perished? There is so much water around you that a ragged-winged bee would be more apt to perish sooner than he would be in a different locality.—Is this the first season you have tried to return swarms in this way, or have you practiced it before? The effect is, you have a great quantity of bees in each hive pretty nearly all of an age; and when they have lived their allotted number of days during the working season, they are gone almost at once. One fall I brought in a great quantity of bees from a neighbor, to save them from being brimstoned. I divided them around in my hives, so as to make them tremendously strong, and fed them to get them ready for winter. They used a great amount of sugar; but when the winter came, my hives that had been overrunning with bees looked about as you describe yours. The bees I brought home were late swarms; and as they had nothing to gather they were of no use, there being plenty in the hive already to take care of all the brood the queen could produce; so when they died of old age I had received almost no benefit from them whatever. In your case I should have supposed the swarms would have given you an immense crop of honey before they wore themselves out; but you don't say a word about the amount of honey you received.—The sticky substance on the basswood leaves seems to be the ordinary secretion of the aphides, only it does not seem to be very sweet. Prof. Cook replies to friend McGee in the next article.

PLANT NECTAR.

Some Additional Thoughts from Prof. Cook.

IS IT PROBABLE THAT IT MAY KILL BEES IN WARM WEATHER?

THE leaves sent by Mr. McGee are thickly gummed with a nectar of very doubtful character, if I may judge from the taste. It is as thick as syrup in cold weather; is very abundant, and quite nauseating to the taste. Upon the leaves I find abundant cast skins of spiders, though no living lice. There can be no doubt but that the nectar is an excretion from the lice. Lice have been very common this year, doubtless owing to the severe and long-continued drought, and have been pretty well studied here by myself and students.

Upon close examination we find that these plant-lice not only emit drops of nectar from the nectaries, the long tubes on their backs, but also that they pass a somewhat similar nectar from the alimentary canal through the anus. The nectar from both sources is seen to be quickly appropriated, and seemingly relished by the many ants that are lured by it to the same plants that are sacrificing their sap and life to these myriad lice.

Until last year I had thought that nectar from aphides (plant-lice) was always wholesome, and of good flavor, while that from scale, or bark lice, we all knew to be bitter, and even nauseating. Last season the blackberry bushes of Northern Michigan were crowded with plant lice that furnished much nectar in the late autumn, which was eagerly gathered and stored by the bees. This nectar, though not so unpleasant as that from bark-lice, was not fit to eat. Some that I received early was not very bad, doubtless owing to the liberal admixture of honey from flowers. I thought this not very bad, and said I should not fear to use it for winter food for my bees. Later I got some probably nearly or quite pure that was decidedly unwholesome, and I said it was unfit either for table or bees. It is thought that many bees died from the use of this food last winter.

The nectar on the leaves sent by Mr. McGee reminds me much of that from the blackberry shrubs, and I should hesitate to use it for winter food for the bees. That it is killing off the bees at this time, when they are on the wing every day, and can freely void their feces, I much doubt. I should hardly accept it as a cause until I had proved by thorough investigation that no other cause was present, and, by experiment, by feeding a few bees in a cage, on this nectar, that it was toxic, or a poison to the bees.

I have seen—yea, and tasted—of honey derived from plant-lice, notably from larch-tree lice, and from lice from evergreens, that was excellent in color and flavor. May it not be possible that the nectar from the nectaries and skin of lice is wholesome, while that from the anus is bitter and noxious, and that the presence or absence of this latter makes the difference? I think the best test in the matter is our own taste. *Never give* the *bees* *honey for winter that we would not use on our own tables.* A. J. Cook.

Agricultural College, Mich., July 16, 1886.

BEE-KEEPING IN CUBA.

A DESCRIPTION OF ONE OF THE LARGEST APIARIES IN THE WORLD.

THE honey-bee was introduced into Cuba from Spain at a very early period of its history; and being a land of perpetual flowers, with no winter to impede their labor, they soon spread to all parts of the island, and bee-keeping has long since become one of the established industries. There is probably no other country of equal extent on the globe, which has furnished an equal amount of honey and beeswax. The latter has, for more than two centuries, illuminated the churches of both this island and the mother country, besides furnishing the supply needed for other purposes, while the former has found a remunerative market in all civilized countries, chiefly in Germany, England, France, and the United States.

A Cuban bee-hive is very simple, consisting merely of a hollow palm log, or oblong wooden box, 10 to 15 inches in diameter, and 5 to 6 feet in length, open at both ends. These hives are arranged in a horizontal position, three or four feet high, supported on a framework of long bamboo poles resting on posts driven into the ground. When these hives are full of honey, the Cuban bee-keeper, after thoroughly smoking the bees, thrusts, into one end of the hive, a long sword-shaped knife and cuts the combs loose from the inside walls. He then inserts a long iron rod, flattened at the end, and bent in the form of a right angle, clear into the brood-nest (which generally occupies about 15 inches in length of the center of the hive), cuts the combs, and pulls them out one by one. He then performs the same operation on the other end of the hive, and so continues until the whole apiary is gone over. The combs are now submitted to pressure, and the wax separated from the honey. Of course, the honey so obtained is not very pure, being mixed with pollen, propolis, dead bees, and the juices of larvæ, all of which tends to cause fermentation; Cuban honey (than which, when pure, there is no finer in the world) has gained an unenviable reputation. Native apiaries, of from 50 to 300 or 400 hives, are frequent, and sometimes as many as 2000 are kept in a single yard. The season for surplus honey extends from October to April, the height of the flow being from the middle of December to the middle of February; but there is almost always a sufficiency for breeding purposes, and hence the Cuban bee-keeper never resorts to feeding. He "robs" his hives only once or twice during the year, and seems satisfied with an average production of 75 to 100 lbs. of honey, and 4 or 5 lbs. of beeswax per hive.

Nearly three years ago the writer introduced, for the Messrs. J. N. & P. Casanova, 100 stocks of Italians in movable-frame hives, together with all the modern appliances necessary to insure success. They were located about 18 miles S. E. of Havana, 8 miles from the ocean, and, we believe, constitutes the first apiary on modern principles ever seen in the island of Cuba; and to the gentlemen referred to belongs the credit of this great change in the systems of bee-keeping, from which promising results will undoubtedly be realized by many of their brethren in the near future.

MODERN BEE-KEEPING VERSUS THE OLD WAY.

The year following the introduction of these bees, 113 of them gave, in a period of 4 months, 43,000 lbs. of choice honey, being over 380 lbs. per hive, or more than four times the amount produced on the old plan. The success of this experiment far exceeded the most sanguine expectations of the Casanova brothers, and, being gentlemen of means, they at once set about and completed one of the best-appointed modern apiaries to be found in any country; and for the benefit of the readers of Gleanings, we will briefly describe it.

The apiary and buildings cover nearly three acres of ground, in the form of a rectangle, sloping to the southeast with a descent of 10 feet in a hundred. Near the center of this plot are two sheds, each 200 feet long, extending across the plot in parallel lines, east to west, and about 30 feet apart. Opening out from the northernmost of these sheds are 6 others, extending to the north line of the plot in parallel lines 25 feet apart. At the center of the south one of the two first mentioned is another shed extending to the south 60 feet to the extracting-room. These sheds are all 9 ft. wide, 6 ft. high at the eaves, peaked palm-leaf roof about a foot thick. They are high and airy, affording perfect protection from sun and rain, and are always comfortable, even in the hottest weather. Along both sides of the sheds, just inside of the eave-lines, are the long rows of two-story hives, painted white, 5 feet apart, and, of course, facing outward, so that the flight of the bees in no way interferes with the workmen. The ground, all sloping toward the honey-house, makes the wheeling-in of the loads of well-filled combs comparatively easy. The extractor is a 6-frame reversible, made by Aspinwall & Treadwell, of heavy galvanized iron, and delivers the honey through a large pipe on top of the center of a broad screen, covering the top of an evaporating-tank holding 8000 lbs., where the honey is freed from any little pieces of comb, etc., which may have got in by accident. From the concave bottom of this tank an iron pipe extends down the sloping ground 60 ft. further, to a broad covered shed where the honey is received directly into the bungholes of the tierces by merely turning the large faucet on the end of the pipe. Along the lower side of this barreling shed, and coming close up to it, is the roadway, which is enough lower than the floor of the shed to admit of the rolling of the filled tierces into the carts ready for transportation to the depot.

It will thus be seen that, from first to last, there is no dipping or lifting of honey required. We might go on to describe the uncapping arrangement, with their screen bottoms and troughs leading to the evaporating-tank, and many other useful appliances of the large airy extracting-room; but our "story" is already drawn out beyond the space we supposed necessary to tell it; so we will close by saying that every thing is built substantial, ample, and yet simple, and contrasts strongly with some of the little "cluttered up" arrangements too often seen in our own country. A. J. King.

N. Y. City, N. Y., July, 1886.

Thanks, friend King, for your very valuable communication, especially your description of the Casanova apiary. Now, if it is a possible thing we want a photograph of this apiary, to show the arrangement of the hives, sheds, etc. If it can be accomplished, never mind the expense, but let us have a glimpse of this great Cuban apiary. I read your communication all through with a very strong curiosity to know where so much honey is disposed of; and now if it is second to none in the world, can't we have a sample barrel of it? In our price list we advertise clover and linden honey, and also California honey; why not let us say Cuban honey also?

THE PRODUCTION OF WAX.

How Many Pounds of Honey Does it Cost the Bee-Keeper for Every Pound of Wax Made by the Bees?

SOME VALUABLE SUGGESTIONS IN REGARD TO THE MATTER, FROM FRIEND HASTY.

FRIEND ERNEST:—Concerning yours of the 25th ult., about my experiments to find how many pounds of honey make a pound of wax, there certainly were such published in GLEANINGS, but you fail to find them; and with a hurried search I fail to find them also. Since writing that article I have made more careful experiments, which I intended to write up and lay before our bee-keeping friends, but have never found time to do so.

I regard the doctrine, that a pound of wax equals 20 pounds of honey, as a monstrous and mischievous error, with no foundation to stand on but the carelessness of observers and the sullenness of bees when subjected to unnatural conditions. In planning matters in my own apiary I consider a pound of wax as the equivalent of about three pounds of honey. I also heartily agree with the idea, first advanced, I think, by Mr. Doolittle, that much of the comb actually built in an apiary is built at no cost at all in honey. Just as the blood of an animal supplies material for the growth of what hair he needs, and little or nothing would be gained by obviating it, so the blood of the bee probably supports the growth of a moderate number of wax-scales without causing any special demand for food.

It just occurs to me to venture the remark, that it is the white wax that costs, and the yellow that we get free. When the bee eats honey and makes a business of digesting it into wax, the scales are white; but when he furnishes a few scales, while consuming pollen freely, the scales are yellow.

E. E. HASTY.

Richards, Lucas Co., Ohio, July 14, 1886.

Friend H., considering the suggestions at the close of the above, that perhaps a moderate number of wax scales do not cost the bee-keeper any honey at all, may be you are right in suggesting that a pound of wax does not cost more than three pounds of honey; then it would follow from this, that, if liquid honey is worth only 7 cts. per lb., a bee-keeper could produce beeswax, at least in moderate quantities, for 21 cts. per lb. Now, then, where is the bee-keeper who has ever done this, or who can do it, or will do it? We will pay liberally for reports of experiments in this line. And, friend Hasty, I wish you would take time and write up the article you allude to as above. It is indeed a matter of great moment, not only in our country, but especially in tropical lands, far away from civilization, where honey is worth next to nothing.

THOSE BOXES FOR FORMING NUCLEI.

FRIEND DOOLITTLE EXPLAINS.

SEEING Ernest's article on page 550, regarding how he formed a colony by using one of the boxes I have described for forming nuclei, leads me to give the readers of GLEANINGS some of the uses I have put these boxes to, and to explain some points which I see Ernest and perhaps some others fail to understand. I see Ernest thought it necessary to get his bees from several different colonies, while I get them from but one, only in case of uniting nuclei in the fall or in making very large colonies. The getting of the bees from only one colony does away with much of the labor, for only one queen has to be hunted, and only one hive opened.

Well, since I wrote regarding the plan before, I have found out another "kink" which makes this the simplest plan of forming nuclei known, and involving as little labor. Well, the "kink" is this: I get the bees from the upper story of a two-story hive, having perforated zinc between the hives. Here I know there can be no queens; and to tell the reader how easy it is done, I will go over the ground a little the second time.

Between the hours of 10 and 11 o'clock A. M. I take my box and funnel, and go to one of these two-story hives, open it, take out as many frames as I want bees (which is generally not more than two), and jar them a little so as to cause the bees to fill themselves with honey, waiting a moment or two for them to do so, unless I am to make more than one. If more than one is to be made I pass on to another hive and get out two frames from that, when I go back and shake the bees down through the funnel into the box, and close the hive. In times when honey is coming in plentifully from the field it is not necessary to wait for the bees to fill themselves, for they are already pretty full of honey. The box is now taken into the shop, and a cloth thrown over it. Any room or shady place I find just as good as a dark cellar, which I at first recommended; and I often set an empty hive or hive-cover over it and leave it right in the apiary so as to save all extra travel.

In less than one hour these bees will almost "cry" for a queen of some kind; but as they will sometimes cluster one if given too soon, especially where virgin queens are used, I wait till about two o'clock, when they will fairly beg. I now get as many virgin queens, from four to eight days old, as I have boxes of bees, and put in with the bees. I do not "jumble" them up at all, as I used to, for I find it is unnecessary. All I do in putting the queen in is to set the box down suddenly, so the bees all go to the bottom, and do this only to get the bees out of the way, while I put in the queen. The box is now left till near sunset, when the bees are all clustered in the shape of a swarm. They are now hived in a hive containing a frame of brood and one of honey. To hive them I have the frames of brood and honey set on one side of the hive, together with a division-board, when, with a quick jar, I dislodge all the bees from the box on to the bottom of the hive near the opposite side. I now quickly slide the combs and division-board across the rabbets to this side of the hive when the bees are immediately on them. In three or four days more this young queen is fertilized and laying, and we have a nucleus ready for sending off queens at once with less time and labor involved than would take to get a laying queen in any other way. In fact, I think so much of the plan that $100 would not tempt me to drop it and go back to any of the old plans—not for a single year. Then there is one other thing I especially value it for, which is, the safe introduction of a valuable queen arriving from a long journey. There is no longer any need of fears of safely introducing the most valuable queen, for I know that not one queen in a thousand will be lost if the above directions are followed. In this case I take bees enough to make a fair colony, and use more frames of brood, so that a strong artificial colony is formed at once. It is handy and good to know that you are ready to introduce a queen safely within three hours after she arrives, no matter if you do not know when she is to come.

Well, I was going to tell you more; but this article is already long enough. I don't like long articles, so I try to do as I would be done by. Give us short articles, but to the point, for interesting reading, friend Root. G. M. DOOLITTLE.

Borodino, N. Y., July, 1886.

I was aware at the time, and so stated, I believe, that I was not practicing artificial swarming exactly as prescribed by you; but my intention was to put it severely to the test by taking bees from *six* different colonies instead of from one or two. In other words, I was ambitious to make your plan do *more* than you claimed for it, and so met with the partial failure as recorded in the apiary report of last issue. Perhaps you do not claim that the plan will make *all* the old ragged-winged bees stay in their new location; at any rate, I succeeded in making a few of these old fellows stay, when I failed entirely by the ordinary plan. I see you do not recommend putting the queen among the bees immediately, but wait till they fairly "beg" for a queen—good, bad, or indifferent. I suppose you tell when the bees get into this "home-sick" or "queen-sick" state, by the hum of distress which will be noted in queenless colonies. Then you drop in the queen.—We will all join hands with you in calling for short articles. When a great number speak briefly, and to the point, it always adds life and variety to a journal as well as to prayer-meetings.

COMB OR EXTRACTED HONEY.

RETURNING SWARMS.

ON page 537, July 1 GLEANINGS, Mr. M. H. Tweed makes a suggestion in regard to disposing of comb honey that would not sell if extracted. The suggestion he makes is all well enough, if the sale of honey alone is the object we desire to attain; but will it pay in the long run to offer for sale, in the comb, honey that would not sell if extracted? In view of the fact that the purity of honey (comb honey too) is already questioned, would it not be better for us to endeavor to show the public that our honey is of undoubted purity, rather than to attempt to dispose of the cheaper grades by securing it in combs? As yet the public are not educated up to the point of knowing that dark honey is equally pure as the lighter grades; and the suspicions that are already aroused will be found difficult to allay, even if we offer nothing for sale as such, except the very best we can raise. Let us all, then, strive to offer nothing but the best as such, rather than to dispose of the poorer, by what the uninitiated might call questionable ways.

On page 533, same issue, Mr. C. H. Wood suggests a good plan for returning swarms "when but little increase in the number of colonies is desired." I presume this suggestion and description is intended to cover those accidental cases that will at times occur, no matter what care is taken to prevent; but as there is a question as to whether simply it is so meant, or that his plan should be a general rule, I would suggest that all the trouble, bother, and care attendant upon so returning swarms, and watching to know the hive they issued from, can be avoided by using a queen and drone trap. In case it is not known from which hive a colony issued, dust a few of the bees with flour, then carry them a short distance from the spot they alighted upon, and throw them in the air; they will at once return to the parent colony, and their white jackets can not be mistaken, when, without such precaution, it might be impossible to the parent hive.

Foxboro, Mass., July, 1886. J. E. POND, JR.

Friend P., I am sure that our good friend Mr. Tweed had no thought of palming off poor or inferior honey, but, rather, something like this: We all have two or more qualities of honey, and the color is not always an indication of the quality for table use. Now, dark honey does not sell well in the liquid state, even though the flavor be first class; hence, may not this same honey of excellent quality but of poor color be more profitable if put into the combs, and sold as comb honey?

FOUL BROOD NOT CURED BY SALICYLIC ACID.

EXTERMINATED BY MELTING COMBS AND BOILING FRAMES AND HIVES.

I BEGAN bee-keeping about four years ago. I succeeded very well until I had about 12 colonies, when I lost all but two with foul brood. I think there could be no mistake about its being foul brood, as the caps of the brood-cells sunk in, becoming concave, with a little pin-hole in the center, and little or none of the brood hatching out. The cells when opened contained a brown semi-liquid substance, about the color of roasted coffee, and had a very offensive smell. I tried spraying the comb with salicylic acid and borax, as directed on page 93 of the A B C; but the only effect it seemed to have was to kill the mature bees. In an hour or so after spraying you could see hundreds of them hopping about on the grass in front of the hives. I thought at first perhaps the drugs were impure, and bought at another place, but with the same result. I was then making preparations to move from Clay Center to this place, which is 15 miles, at least, from any other bee-keeper, so I made two new hives, put what remaining bees I had into them, and sent them here. I melted all my combs into wax, and exchanged for foundation. I boiled all my frames, hives, bottom-boards, and covers, and am using them now.

From the two hives, in two years I have increased to ten. We get little surplus honey in this neighborhood until the latter part of August; very little, if any, white clover is grown here. I got about 200 lbs. of extracted honey per hive last fall, mostly from goldenrod, I think. Bees have to be fed in May. I tried a rather odd experiment in feeding this spring, which I will give you for what it is worth. As farmers will, sometimes, I got very short of sugar, and did not have time to go to town after more; but the bees must be fed. So I reasoned, that, as new milk is good for man and beast, why not for bees? I fed the colonies that were in the greatest need about a teacupful each, daily, for nearly a week, of new milk, made quite sweet with about a tablespoonful of sugar. The bees drank it eagerly, and cleaned the platter before it had time to sour. But although I looked the frames over several times, I could see nothing like milk in the cells. What did they do with it?

M. H. Panton.

Oak Hill, Clay Co., Kan., June 26, 1886.

Friend P., your suggestion about feeding the bees milk is a valuable one; and since you mention it, I recall that this same subject was talked of a good many years ago, and it was then thought that milk assisted very materially in brood-rearing, at times when little or no pollen was to be had. I think it quite likely, that where bees are in a starving condition, or pretty near it, during a dearth of honey in the summer months, milk might often in many homes be the cheapest food that could be given them until honey came again; and I am inclined to think they can be easily taught to take new milk, right from the cows, without any sweetening at all. Have any of our readers ever tried it?

HAVING STUDENTS IN APICULTURE.

MRS. CHADDOCK'S EXPERIENCE WITH 'EM.

THIS summer I am having a student to learn bee-keeping. I never advertised for students, and I do not want them. I have no time for it. So when this young woman came to me to learn bee-keeping I tried to put her off, but she persisted. I gave her a copy of Gleanings, the *A. B. J.*, and *C. B. J.* to read, and went to sleep. When I awoke, three hours later, she said, "I can't make head nor tail of this stuff. It's all Heddon and Doolittle, reversible hives, queens, broodings, and lawsuits."

"Oh! well," said I, "keep on; and when you have read these papers for fifteen years you will begin to see the point."

"But," said she, "I want to know how to do to get lots of honey; I want to make money."

"And," said I, "that is just what Heddon and Doolittle are all the time writing about."

"Well," said she, "I think I had better begin *somewhere*. This looks as if we were taking the fish in the middle and swallowing both ends at once. Isn't there any beginning to bee-keeping?"

"Yes," I answered, "there's plenty of beginning; there's Root's A B C," and I turned over and went to sleep again. Next morning she followed me out among the bees; and after looking round awhile she asked which were the Simplicity hives. I told her and she put it down in a note-book. I told her that note-books were no good; but that if she wanted to help she had better get on a bee-hat, and help me carry away a few old colonies that needed moving. She came back presently, hatted and gloved, and with sleeves tied down. We picked up a Simplicity hive, bottom-board and all, and started; but just then a bee stung her on the ankle; she screamed, and said she must set the hive down; she would let it fall, she knew she would; but I said, "If you let it fall I'll ——," and she held on till we had it in the right place. Her ankle and foot swelled up tight, so that she could not walk any for three days. I told her she could quit the student business at any time, but that, if she pretended to help, she *must* help, and not weaken when the tug of war came.

I am selling comb honey at 10 cts. a pound, where a man takes a whole box, or 12½ for a few pounds. Good honey is selling in the same market for *seven cents*. It is *just as good* honey as mine, but it is in the old-fashioned honey-boxes, each one weighing from 15 to 20 lbs. I have three towns to sell in, besides the country folks. If I take honey anywhere, and the man who is selling it has half a box on hand, I do not leave it but haul it home again; and when he is *just out* I take it back again. The best plan is not to take it till they ask for more. People will buy honey when it is nearly gone, who won't buy out of a full box. If there seems to be plenty, they say, "Oh, yes! I'll get some one of these days;" but if it is nearly gone, they are afraid that it will be all gone soon, so they buy it then. I think people often kill their own market by piling too much honey on it at once.

Mahala B. Chaddock.

Vermont, Ill., July, 1886.

Why, Mrs. C., how in the world did you get to go into the "student" business? It is not long since you were going to hire out to drive a mule team. I suppose the young lady is still studying—at least, you don't say she went home and gave it up. Why didn't you start a wagon, such as we pictured last month? You could have the mule team to draw it around; and when you get a whole class of students, you could have them do all the work while you simply superintend. If you sell the honey at such low prices, however, of course your students would have to work for nothing, and board themselves; or, still worse, pay you something for teaching them so patiently.

HONEY-DEW.

HOW TO GET IT OUT OF HONEY-BOXES.

WE have had an excellent season for bees to build up on. White clover was more abundant than at any previous season—so much so we procured a little surplus from it; but before I was aware, my bees were storing honey-dew in the sections that had been nearly filled from white clover. Of course, I wanted that out, and tried an experiment which proved successful in my case, but would probably be too laborious for one who has a large apiary, and wants no more increase, and who has a large amount of this honey stored in sections.

I first extracted all the honey from a set of frames containing unsealed brood, and placed them in an empty hive. I then took a strong colony of bees, and, after securing the queen, shook all the bees (except a few) in the hive I had prepared, and released the queen in the old hive. I then removed the new hive some distance and let it remain over night. The next day the workers nearly all returned to the parent hive, leaving a fair colony of bees with but few workers and a hive full of brood, with nothing to feed it. Now is the time to give them a queen and put on the boxes containing the honey-dew. The young bees carried it down, as I expected they would, to feed the brood and store it in the combs below. The object of leaving the queen with the parent colony is, that worker-bees will have less inducement to remain with the new colony. Of course, they will empty the boxes, and we lose what white-clover honey had been deposited in them.

The honey-dew honey is not so dark, nor does it have such a strong, sharp, unpleasant taste as in the year 1884, when it was so remarkably abundant. It will be remembered, that the winter following there was great mortality among bees, which some accounted for by feeding this dark honey for winter stores. Whether it is a secretion from a different insect from that of 1884, I am not able to say; but I incline to the opinion it is the same insect, and that bees worked on white clover at the same time they were gathering it, which causes a mixture of the two varieties, and accounts for its not being so dark as it was in that year. If this was the cause of the great mortality of the winter of 1884-'85, bee-keepers may expect the same result the coming winter, unless some precautions are taken in excluding it from winter stores. But as I then wintered one colony successfully on that secretion alone, I feel like trying some more the coming winter.

Bees are now working on a species of smartweed which usually begins to bloom about the 2d or 3d of July, but which bloomed this season about ten days earlier. GEO. WISEHEART.

Iola, Ills., July 12, 1886.

Friend W., your plan of getting honey-dew out of the sections is quite ingenious indeed. It seems too bad to lose the white honey also where a great portion of it is light. Would it not be possible, by keeping careful watch of the bees while they are bringing it in, to get them to take out the honey-dew before it is sealed up, without disturbing the capped honey?

FRIEND TERRY TALKS TO US ABOUT HOME INFLUENCES.

ALSO A HINT TO THE WOMEN-FOLKS IN REGARD TO SPRINKLING CLOTHES FOR IRONING-DAY.

FRIEND ROOT:—I have been thinking for some days, while at work, about an idea thrown out by you in GLEANINGS for June 1, about little things shaping the future lives of our boys and girls. I am perfectly sure that they do. The simplest thing, done in a neat and tidy manner, before the children, will have its effect on their future lives, and it will be the same also if there is no attempt at order or neatness. A crooked stovepipe is an educator to the little ones as surely as the schoolteacher, or a door that won't shut, or a gate off the hinges, or a shiftless-looking dooryard; all such matters will leave an impress on the children's minds that will make it seem natural for them to have similar surroundings when they grow up. We parents ought to think of this. When I was a small boy I thought, boylike, that father was over-particular about many things. I used to say to him, "Father, what is the use of spending so much time to get those potato-rows so straight (in the garden)?" Or, "What is the use of doing so much work in that dooryard?" You see, I was a boy then, and thought more of play; but father was looking ahead, and brought me up surrounded by such an atmosphere that I am necessarily as particular, if not more so, than he was; and many a time have I felt thankful for it.

When I see every thing at loose ends around a farmer's home, I can not help but think the chances are nearly all in favor of the children being just like him. If there is a nice lawn, and walks and flowers, and neatly painted buildings, and pretty trees, and every thing looks neat and tasty, I can tell almost to a certainty how things will look around the children's homes when they get some of their own, the surroundings of childhood have so much to do with the future grown person. A shiftless man whom I once knew, was being reproved for his conduct by a friend, when he broke out in defense with: "You know my father and my Uncle James and my Uncle Henry, don't you?"

"Yes."

"Well, then, what more could you expect of me?"

To be honest, one had no business to expect any thing very much better of him. Now, I want to say to every reader of GLEANINGS, Think twice before you say "no" when the good wife wants you to fix things up a little—to mow the dooryard, to get her some flowers to make home beautiful. I know a man who is worth $50,000 at least, who grumbled about it because his wife wanted him to get her a few flowers at 6 cents apiece. Ah! money is the only thing worth living for, in his eyes.

You may say that the love of the beautiful and of order and neatness are not so important as good moral training. Perhaps not; but the former will strengthen the latter. They are sorts of sugar-coated pills that will do good without being hard to take. At any rate, the children can not refer to your failings in future years, and say, "What more could you expect of me?"

Now, friend Root, I want to tell you about something that I found going on in my dooryard the other day. You may remember we got some wire clothes-line and a Whitman's fountain pump of you, among other things, last spring. Well, I found one of my daughters sprinkling the clothes, on the line, with the pump, after which they were rolled up and put in the basket ready for ironing. It was quite a saving in time over the old way; and with a little care it can be done very nicely. This is a use for the pump that I do not believe you ever thought of. To be sure, it is a little matter; but I am glad always to do what I can to make the work of the ladies, necessarily quite too monotonous, as pleasant and easy as possible. In my next letter I want to talk to the husbands and fathers a little about some improvements indoors. T. B. TERRY.

Hudson, Ohio, July, 1886.

Thanks, friend Terry. Your idea is certainly novel, in regard to sprinkling clothes, and I am going to have my wife make a test of it at once. The cheap Smith pump, which costs only a dollar, will no doubt answer just as well for this purpose as the Whitman, and it will throw the water in such a fine spray it seems to me it must answer the purpose excellently.

HEADS OF GRAIN
FROM DIFFERENT FIELDS.

CALIFORNIA NOT SO BAD AFTER ALL.

I THINK that Mr. F. J. Farr's article on California, page 489 of GLEANINGS, is a little overdrawn. I will admit, that there are many places in the southern part of the State where one could travel 22 miles, or even more, without coming to a house; but he should remember that this is a big State, and comparatively young.

The Harbison section, of which Mr. Farr speaks, is fast going out of use, and the one-pound section is used instead. There is no lumber in California that is nice for sections, so we are obliged to import them from the East, which makes them cost a little more than they do where made.

A good workman can always find plenty to do, and at good wages. I can always find employment at work in orchards at $2.00 a day. W. W. BLISS.

Duarte, Cal., July, 1886.

DO BEES FROM THE SAME QUEEN CHANGE COLOR?

Whether the subjoined facts in regard to bees changing their color is any thing of interest to you, or whether it has been observed by others, I do not know, since I have not seen it in print. I have several hives of Italian bees which I raised artificially. They were, during last summer, of the right color—bright, not a hybrid or black one to be seen among them. Later, in the fall, one day on opening them I found several frames full of bees of a different color. I was somewhat disappointed. First, I thought a stray swarm must have found its way to the hives, or the queen might have died, or that the swarms raised a new queen, which met with an impure drone. I have had it all winter and spring on my mind, what caused the sudden appearance of (to my eyes) a different bee than what I had raised last summer, not only in one hive, but several. These very same hives don't show now any other bees than Italian, nor do the new swarms show any other strain. But this I found out, that the young bees not only look downy, but black; the three bars are hardly perceptible at first, but enlarge as they grow older, so that this summer, to the eye of a stranger, it looks as if I had hybrids, blacks, and Italians, all mixed up. Later in the summer, especially on some plants, bees as well as other insects will change color, even if only temporarily. I instance the aphides, or lice on fruit-trees, roses, etc.

Sandusky, O., June 21, 1886. F. J. M. OTTO.

Friend O., I have often remarked that bees which I had in the spring and summer been calling my best and finest Italians, during a dearth of honey in the fall were almost invariably small and dark.

BLACKS VS. ITALIANS AND HYBRIDS; WHAT IS THE BEST BEE?

I have been asked this question so many times, and have asked the same question so many times with such diversified opinions, that I have long ago ceased to answer or ask. I am more in love with the hybrid (Italians and blacks) than any others; my second choice is pure Italians; third choice, any thing but clear blacks. One-fourth of a mile from me is an apiary of 100 colonies. The owners would prefer clear blacks, designating my bees, which are mostly Italians and hybrids, as nothing better than "horse-flies." Now, if blacks are best I want to keep blacks; and if Italians are best, I want them; but really, from my experience I prefer hybrids. I have handled bees for the past 20 years, but upon improved principles for only the past five years, and I have never as yet had occasion to complain of the vindictiveness of the hybrids. As honey-gatherers they *Excel* (with a big E). While my blacks were idle during a recent drought, Italians and hybrids were continually storing a little honey.

I report a poor honey-yield in this section, on account of drought. I have 85 colonies—50 hybrids and Italians. F. H. CHAPIN.

Hinsdale, N. Y., July 6, 1886.

BITTER HONEY.

I should like to have you tell me what the sample of honey sent is gathered from. Not being accustomed to it I can not tell. It is mixed in some four or five hundred sections. Some of it is so bitter we can not eat it. Will it improve by age?

WM. L. WARNER.

Charlemont, Franklin Co., Mass., July 14, 1886.

I can not give you any conjecture as to the source, for I have never tasted any thing like it before. So far as I am concerned, however, I should not object to it for my own eating, for to me the bitter taste is rather pleasant than otherwise. I might, however, get tired of it after having too much. I will explain to our readers that the peculiar taste is a little like cinnamon—say the thick barky cinnamon that is sometimes slightly bitter. Where honey is unsealed, and remaining in the hive, no doubt this taste would disappear to a great extent by letting it get thoroughly ripened. If it is in sections, however, that have been removed from the hive, I should not expect much improvement.

HONEY-DEW.

My peach-tree leaves yield honey every year. At the base of the leaf are three little tubes on each side. There is where they get the honey. There are persimmon-sprouts all over my place, and there is a kind of louse which wraps itself in the leaves—that is, folds them together. A great many are in each leaf. They produce honey three or four months. Shake a leaf in your hand, and out roll the little shot-like balls, from the size of a pin-point to the size of a duck-shot. I have just been out and got some leaves—a persimmon and a cottonwood. The bulged-out place on the cottonwood is where the honey was. I saw as much as a teaspoonful in one. This spring they lasted but two or three weeks. In 1880 I saw a pine-tree just covered with honey one morning: if you had shaken it you would have received a shower-bath of honey. It was dropping off on the grass, and even the ground was wet with honey. The bugs that produced it were about the size of a pea—oval-oblong, with a crease down the back. I could not make them show any sign of life. They were stationary—no legs, no mouth. They were attached to the limb with a heart-like contrivance, Take the body of a tick, and you have something similar; break one, and you see a mass of matter. They were tucked in among the straw on the limbs—thousands of them. The tree was about 30 feet high; the branches, at the base, were spread about 12 or 15 feet in diameter, and tapered off gradually to the top. R. R. WILLIAMS.

Edwards, Hinds Co., Miss.

STARTING A HONEY-WAGON.

I come again to ask your advice upon a question which I wish you would give your *personal* attention for a moment; i. e., the advisability of starting a honey-wagon on the road. A great many farmers bring honey to market and take 10 or 12½ cts. per pound in unsightly sections; and when I offer my white clover and basswood honey (sections cleaned and honey white) for 15 or 16 cts. I am told they can buy honey cheaper. I thought, a wagon kept on the road in town and country could sell my own honey; and if parties are willing to sell *so cheap*, buy theirs and sell it out some way. I do not feel like devoting my entire time to the business, and have the market price controlled by a few bee-keepers who make no calculations on honey sales; and their willingness to take almost any thing, *must* cripple the sale of honey put up in better shape.

Nevada, O., July 20, 1886. WM. M. YOUNG.

Running a honey-wagon is quite an expense, it is true; but I think in many respects it will pay well, for the very reasons you mention. Always have at least two, or, still better, three grades of honey on your wagon. We get 18 cts. a pound for our very finest comb honey; but we have side by side of it cheaper grades for 12 and 15 cts.; but the cheaper grades remain almost unsold while we have the real "gilt edge" in stock. When that is gone (and, of course, it is always the first to be gone) then we have to fall back on the other. Your wagon might make the round, say twice a week, or even once a week; and I think it would pay you well to keep track of the honey-producers, and take their product off their hands at what it is worth. If they see you getting 18 cts. per lb. while they get only 10 and 12 cts., it will very soon have the effect of inducing them to take more pains.

HONEY-DEW, AND WHAT SHALL WE DO WITH IT WHEN IT IS GETTING IN THE SECTIONS?

I am an A B C pupil. My bees are putting honey-dew in the sections, which have been partly filled with clover, and are spoiling the whole lot. Shall I take the sections off and put them back when the fall honey-flow commences? Would they not be more apt to swarm if the sections were removed?

Conneaut, O., July 19, 1886. H. A. CUMMINS.

Friend C., it is a little hard to say what is best in such a case. Your sections are probably part full of white honey. The honey-dew will ruin the sale of it, unless somebody has a mind to take it at a low price and get out the honey-dew spots. They can see these by holding them up to the light as we have before explained. If you let them get filled up with fall honey, this will also injure the sale of them; but of course it will not be as bad as honey-dew. The bees would certainly be more liable to swarm if you take the sections off; but perhaps you might put on some empty combs, and then throw out the honey-dew with the extractor, saving it to feed next season, or at any time so it will not get into the winter stores.

SOLAR WAX-EXTRACTOR TO BE TRIED AT THE MICHIGAN AGRICULTURAL COLLEGE.

Prof. Cook ordered a solar wax-extractor of us, and we sent him the original one sent us by friend Green. In regard to it he replies as follows:

Allow me to thank you, for the college, for the solar wax-extractor. We shall test it thoroughly, and improve it if we can.

In regard to the weight of the eggs a queen may lay in a day, he writes:

I already have the matter of egg-laying in tow, and you shall hear. We have scales that will weigh a breath. A. J. COOK.

Agricultural College, Mich., July 19, 1885.

SHADE AND VENTILATION A PREVENTIVE OF ABSCONDING.

During a very pleasant and instructive visit paid to the apiary of Mr. S. T. Pettit, of Belmont, my attention was practically drawn to the advantages arising from shade and ventilation for hives. Mr. Pettit stated that he never had any trouble arising from his bees vacating the hive after swarming. In the past, such had been the case; but now he was pleased to say no difficulty arose from that cause, and the trouble had been a want of comfortable quarters for the bees. The hives, combs, etc., are kept in a cool place until required for use, when the swarm entering them finds a cool, shady retreat which is made additionally comfortable by, if possible, being protected from the strongest rays of the sun, plenty of room, and free access of air. Mr. Pettit stated that he was perfectly satisfied that bee-keepers would find no difficulty from swarms absconding if this method were pursued. Of course, the very best of bee-keepers can learn something of value when visiting an apiary in the height of the season, and I learned a great deal. I always do on these visits to our leading bee-keepers; and for my part, I never desire to give such information as originating with me. R. F. HOLTERMANN.

Brantford, Ont., Canada.

REPORTS ENCOURAGING.

A COLONY THAT PRODUCED 462 POUNDS OF HONEY.

WE have had a good honey harvest this time. I took 462 lbs. of extracted honey from one colony, besides the winter supply. Several other colonies were not far behind in the amount taken. A few others gathered only enough for winter. My average is probably nearly 100 pounds per colony. C. W. DAYTON.

Nashua, Iowa.

Friend D., I wish you would tell us more about that colony that gave you that yield. Was it a hybrid or Italian? and if the latter, where did you get the queen? We should also like to know the kind of honey these bees obtained, and the style of hive or the surplus-arrangement you used. We like little snatches of news from our bee-friends, but we want to know more about it.

Bees here are doing well. I have averaged 130 lbs. per colony, and am still extracting.
Verdugo, Cal., June 27, 1886. G. B. WOODBURY.

My bees are doing finely; have taken 90 lbs. of comb honey from one swarm. A. A. IRISH.
Big Spring, Mich., June 25, 1886.

Bees are doing finely on alsike. I never had them do better on clover. F. D. WOOLVER.
Munnsville, N. Y., July 3, 1886.

A TON OF WHITE HONEY IN SECTIONS.

Bees have done finely. I have a ton of white honey in sections. The bees are doing but little just now—too dry. W. E. KIMSEY.
Salem Center, Ind., July 7, 1886.

600 LBS. OF HONEY PER WEEK.

We started June 1st with 24 colonies of bees. We have at this date 55 colonies and 2000 lbs. of honey, and are extracting from 600 to 800 lbs. per week.
Creighton, O., June 22, 1886. A. H. DUFF.

EXTRACTING.

I am extracting the finest crop of white-clover honey I ever produced. Every cell is sealed, and so thick I can hardly throw it out with your extractor. E. J. SCOFIELD.
Hanover, Wis., July 9, 1886.

"BEES DOING VERY FINE."

We are very busy at wheat harvest. Bees have been doing very fine. Some stands made from 60 to 80 pounds of clover and fruit-bloom honey in sections. JOHN H. BULLERMAN.
Switz. City, Ind., June 21, 1886.

NEVER HAD BEES DO SO WELL.

I am working 200 colonies without any help, and it keeps me very busy. I never had bees do so well as they have been for two weeks. I have taken off some honey of the best quality. White clover is in bloom, and linden is full of buds, and the prospect is good for a large crop. CHARLIE W. BRADISH.
Glendale, N. Y., June 22, 1886.

4 LBS. OF HONEY PER DAY.

I think I have had good results with the hive you sent, in a short time. I put a swarm in May 30th, and June 27th I took out 46 1-lb. boxes full. The rest were under way—white-clover honey; brood-combs were full. I calculate they made 4 lbs. per day from the start. I like the hive very much.
Bristol, Pa., June 30, 1886. W. P. PRAY.

HAVE TAKEN 18 TONS.

The season opened finely. We had a big flow of honey in some localities in May, but it has shut down. I do not think there will be any late honey. What we have extracted is very clear and of fine flavor. Last year was one of our off years. I did not get to extracting. I have taken out this season, up to date, 18 tons. There will be about half a crop in this county. G. W. LECHLER.
Newhall, Cal., June 20, 1886.

BEES NEVER SO FORWARD IN THEIR WORK FOR 28 YEARS AS NOW.

I have never had my bees so forward with their work for 28 years as they have been this year. I wintered 18 swarms without loss. They commenced swarming May 20th, and two-thirds of them swarmed in May, and a swarm in May is a rarity here. In five consecutive days eight swarms came out. The others swarmed early in June. They have been doing pretty well on clover, and the present prospect seems good. J. L. HUBBARD.
Walpole, N. H., June 25, 1886.

FLOW OF HONEY WONDERFUL, AND FROM TEXAS TOO.

We are now having a wonderful flow of honey from the mesquite, and every thing is lovely again; and if it will only hold out long enough, your humble friend will yet come out with waving banners. I had 39 colonies after swarming time, but have doubled back to 24; but they are now 24 full colonies, not 39 nuclei, as the most of them were after the dearth. M. BROERS.
Gonzales, Texas, June 14, 1886.

THE SUPERIORITY OF ITALIANS OVER BLACKS.

Bees are doing well. I have new swarms hived on empty comb that have made 50 lbs. of surplus honey, and cast a swarm. I had 2 swarms of black bees come and enter hives that were full of comb; one of them was mostly killed. I had put a swarm of bees in the hive the day before they arrived. The other one stood beside a swarm of Italians, and had the same chance. The Italian swarm made 50 lbs. of surplus, and cast two swarms, while the black one has made very little surplus and no swarms. L. W. VANKIRK.
Washington, Pa., July 10, 1886.

A GOOD REPORT FROM ALABAMA.

My bees are doing well now. My best hive has made me 172 lbs. of comb honey. I put a section partly filled with honey to start them, in the sections. This is the best yield of honey I have ever known in this section. Forty or fifty pounds is a good yield ordinarily. My bees are pure Italian; black bees have given no surplus so far as I have heard this season. In regard to early queens, I think we can beat you a little usually; but this season was very unfavorable for early work. The bees gathered just honey enough to live on until about the middle of May, when white clover came in and they have just boomed since, although we have had a great deal of rain. S. G. WOOD.
Birmingham, Ala., July 8, 1886.

REPORTS DISCOURAGING.

HOW THE DRY WEATHER HAS AFFECTED THE CLOVER-YIELD.

THE season here for the production of honey has not been at all favorable, as the dry weather cut short the white clover, nor is basswood yielding honey to any extent, as the blossoms wither almost as soon as opened. Our bees will work for a short time early in the morning and evening, but they do little more than keep the supply good in the brood-chamber. Our crops are all short, and quite a large per cent of the wheat will not be harvested, as it will not produce the seed sown. One thing, however, can be said in favor of these clear scorching days: they make our solar wax-extractors work to a charm.

We have not been troubled with any swarming yet this season, as the bees have plenty of room yet in the brood-chamber.

DRONELESS COLONIES, AGAIN.

On page 546, N. C. Arnold speaks of having a colony droneless. We can say that we have three good strong colonies in our yard that have not raised a drone this season. We have kept a drone-trap on the hives nearly a month, and I failed to trap a single drone, and we have very carefully looked the colonies through, and failed to find any drones. Another point we wish to notice is, that drones were raised in the least numbers this season we ever saw; but whether it is on account of the scarcity of honey or not we can not say; but the fact *has* been, and is *now*, that there are very few drones in our apiary. After carefully looking down one side and up the other of bee-keeping, we must say the outlook is decidedly dull; but we are not ready to give up by any means. Possibly we may have rains yet that may bring out fall bloom that may help us out; but we have thus far never received any benefit from the fall bloom, as it consists principally of goldenrod, which never has produced any noticeable amount of honey for us yet.

Rochester, O., July 5, 1886. M. W. SHEPHERD.

My bees have not paid expenses yet.

BENJAMIN SHERK.

Nevada, Story Co., Ia., June 15, 1886.

NO HONEY.

My bees are lying out, and have been all summer. I have smoked them in numbers of times, but it does no good. They have not made any honey. I have read your book, but failed to find what to do. I am in trouble about them. E. J. MCCREVEY.

Tyro, Miss., June 16, 1886.

ONLY 9 LBS. FROM 15 HIVES.

Do you find that your bees are doing well this year? The bees in my neighborhood are doing very little. One man has 15 hives, and has taken off only 9 lbs. of honey. My bees have not commenced yet to build comb. I can not understand it.

WM. H. HENICK.

Boston, Mass., June 29, 1886.

See Our Own Apiary, this issue.

THE SEASON VERY DRY; BASSWOOD A FAILURE.

I have not had a natural swarm this year. However, we had a very good flow from clover—rather heavier than usual. I have taken only 100 lbs. of box, and I have not obtained a pound of extracted honey. About one-fourth of the basswood-trees bloomed, and very sparingly. Basswood is in bloom now, and it is impossible to work in the yard on account of robbers. Our only hope now is buckwheat. We are having a very dry season.

W. S. COGGSHALL, 200.

West Croton, N. Y., July 12, 1886.

DR. BLANTON'S YIELD BELOW THAT OF LAST YEAR.

Bees are not doing very well here this year. Dr. O. M. Blanton tells that he will not get nearly as much honey this year as last. Bees have swarmed very little here this year. What makes bees swarm without building queen-cells? In all other respects they are in good condition as to being full of honey and brood. F. S. ELDER & BRO.

Lake Village, Ark., June 30, 1886.

The Italian bees swarm quite frequently, without any preparation being made for swarming in the way of starting queen-cells.

HONEY-YIELD NOT LARGE; TODD'S CANDY.

The honey-yield will not be large here. Basswood is nearly a failure—but few blossoms. I had a fine yield of clover honey, and am hoping for a fall yield. I have just received a sample package of Todd's candies. They are very nice, with the unmistakable honey taste. Have you ever received samples? I think it is a splendid way to work up honey. I think friend Todd is reliable in his statements. We ought to boom his candy.

Hartford, N. Y., July 17, 1886. J. H. MARTIN.

See Editorial Department.

A POOR HONEY SEASON.

The season of 1886 has been the poorest for bees in this locality ever known. Last fall we had a fine honey-flow in September, and bees went into winter with plenty of stores. They came out in the spring, strong and in fine condition, and the season promised well up to April 20. At that time a severe drought set in, and from then to June 2 the bees did not gather enough honey to rear brood with; in fact, I do not think they got any at all. They consumed all the stores on hand; and where they were not fed, the queens quit laying. I have heard of a good many bees dying from starvation during the month of May—a thing heretofore unheard of here. The strongest colonies killed off their drones during the drought, except where they were deprived of their queens; and even where the queens were removed they would kill most of the drones. I kept my 80 colonies alive by feeding the weaker ones at dusk, and by feeding all outdoors about 4 P. M. each evening. June 2 we had a very fine rain, and for two weeks the bees stored in some honey, and some of the strongest colonies started to building comb, and would draw out foundation readily. For the past eight days they have not added any thing to their stores, though we have had fine rains lately. This is the first season in my experience where there was a failure in the honey-crop, when the field-crops were good. From all I can learn, the honey-crop is a failure all over Central and Northern Texas.

J. P. CONNELL, 68—80.

Hillsboro, Texas, June 24, 1886.

ANOTHER ADVERSE REPORT FROM TEXAS; THE LIVE OAK.

Crops of all kinds have failed in this and adjoining counties. Our bees have also done poorly. There have been a great many bees starved to death. I have had but one natural swarm this year. It has been so dry there have been no blossoms for bees to work on. I have lost only one swarm this summer. I have been in this county eight years, and bees have done well every year till now. As I told you before, I had 28 stands, and I have not taken a pound of honey as yet, and I am not likely to unless I get it from the honey-dew or live-oak balls. We have an abundance of sumac in this country and they will bloom the latter part of this month and August. Bees do well on them while they last. They gather both honey and pollen from them.

THE LIVE-OAK BALL.

We have an abundance of live-oak timber all over this country. They bear a little ball, in size from ¼ to one inch in diameter, resembling what is called the ink-ball of the black-jack tree. They seem to grow out from the small limbs of the trees, without any bloom to make them. The greatest yield from them has been in the dry years, since I have been here, so we look for a heavy crop this fall. In August they will make their appearance. They are of a whitish color; and in September and October, when the sap or water dries out of them you can see the pure honey exuding from them. Some times you can find a drop as large as a drop of turpentine hanging at the bottom of the ball. Some times you will see it in fine particles, where it exudes from the sides. You never see honey on them at all until they commence to dry up. It is a fine article of honey, and sells well. I often sell it at 25 cents per lb. J. A. Isaacks.

Broomwood, Texas, July 13, 1886.

OUR OWN APIARY.

SOME OF THE SYMPTOMS OF DEAD BROOD AS FOUND AT THE HOME OF THE HONEY-BEES.

It has been somewhat of a question with us whether the foul brood, mentioned on p. 610, is the real virulent form, or a milder type of it. At any rate, the symptoms as we find it are about as follows: The affected brood in some cases is shriveled up, and of a brown color; in others, a maturated, thickened, milky mass in the cells, and in color a grayish black. In some combs the brood is all affected, and in others only an occasional cell appears. It has been said of foul brood, that the cells are sunken; but we do not find this to be the case with our diseased brood-combs; but we do find that the cappings are punctured.

THE ODOR OF THE BROOD.

Well, as nearly as I can describe it, it is not unlike the smell from an old glue-pot—a gummy, rank odor. To me it is not "foul" or sickening, strictly speaking; but it certainly has an unmistakable flavor of blasted hopes.

After reading the foregoing description, perhaps some one who has had some experience with foul brood can inform us whether we have the real virulent form of the disease.

Up to the present time we have burned *eighty-three* combs. To treat them thus, and replace with new frames of foundation, we consider much cheaper than to try out the combs and boil the old frames in water. The old frames, and the paltry amount of wax so saved, would be almost insignificant, and the process of trying out the wax, it seems to me, would be attended with more or less risk. If a few robbers should get into the room where the combs were, and gain access to some of the diseased cells, and make their escape, well, I should not be surprised if you had "to fight it out on that line" all summer. No, sir! where 400 colonies and over are at stake, it doesn't pay to have diseased combs about, even for a minute. If you want to know our advice we would say, If you have reason to suspect that a colony is affected with foul brood, don't examine it when the bees are flying—at any rate, when there is any possible chance for a robber to get at the combs.

Now, I suppose when this issue is out a few will begin to declare that *they* have foul brood. Let me tell you beforehand, that the probabilities are—well, I might say a thousand to one that you do not have it. Do not be in haste to declare that your bees have the disease, until you have visible signs of its spreading to other colonies. If the disease, as we have it, were not seen to be contagious, we might question whether we had it.

THE 50 CHAPMAN HONEY-PLANTS AS SEEN ON OUR HONEY-FARM.

These plants have been in bloom for a week back, and from present indications they promise much. They are thistle-like, about two feet in height. Each plant is surmounted upon one or more of its stalks by balls, or what botanists term heads. These are from 1½ in. to 2½ in. in diameter, and vary in number on each plant from 6 to 10 heads. The heads, when in bloom, are covered with small star-like white flowers, in the center of which the anthers, blue in color, surround the pistil. The plants with their white balls present a very pretty appearance. We were surprised to see how the bees took to these balls. Sometimes as many as eight or ten bees can be found upon each head, sipping at the nectar in a very leisurely manner. After the bees have been upon the blossoms for a little while they will tuck their tongues under their chins and remain quiet without any visible motion. If we brush them off they will in some cases drop to the ground, as if so gorged as to be unable to fly. On remaining upon the ground a moment or so they will take wing as if nothing had happened. I then concluded that they were not actually gorged, but apparently stupefied; that is, the plant seemed to have something of a narcotic effect upon the bees. I have sometimes noticed a similar effect when bees were working on sweet clover, and I believe others have reported something of the kind.

To-day, July 27th, on going over to our patch where the Chapman honey-plants are, I found that the bees visited the heads, and returned without showing any signs of the narcotic effect mentioned above. In fact, their actions were lively, and I could not find that any of the bees would drop to the ground when I brushed them off. Perhaps the day has something to do with it.

The boss printer says, "No more room," so I'll have to stop right here. E. R. Root.

GLEANINGS IN BEE CULTURE.

MEDINA, AUG. 1, 1886.

We have treasures in the field, of wheat, and of barley, and of oil, and of honey.—Jer. 41.8.

Our subscribers now number 5814, a gain of 191.

THE EDITOR OF GLEANINGS OFF ON A WEEK'S VACATION AMONG BEE-MEN AND OTHERS.

About the time this issue is out I shall probably be at the honey-farm of H. Chapman, Versailles, N. Y. Here I expect to meet other bee-men, and in committee examine into the merits of the Chapman honey-plant, which will then be in full bloom. Leaving there, I hope to visit friend Cole, distinguished as the originator of the so called "New Agriculture;" and, time permitting, take in one or two other points.

FILLING ORDERS FROM NEIGHBOR H.'S APIARY.

As stated in another column, on account of foul brood being found in our apiary we shall fill all orders for bees and queens from neighbor H.'s two apiaries. They are situated 3½ and 2 miles respectively, from the Home of the Honey-Bees, and it is altogether improbable that the disease from our hives should be transmitted to his bees. Neighbor H. has examined several of our affected colonies, and, after carefully inspecting all his colonies, assures us that he has nothing of the kind among his bees. We think our friends may feel safe in still ordering bees of us as heretofore.

TODD'S HONEY CANDY.

We have received samples of this, and it is a very nice confectionery, with an unmistakable flavor of honey. There is some tendency to stickiness, but not very much. The trouble is entirely obviated with the caramels, which are wrapped in prepared paper, as usual, to prevent sticking or daubing. One difficulty in the way of getting it to take the place of common confectionery is, that the raw material is yet rather higher than sugar. If people will pay a little more for this kind of candy, it might come into general use. I don't think that a recipe could be given for making it at home. It could be done, probably, by a regular confectioner.

THE HONEY-CROP A FAILURE IN ENGLAND.

We are sorry to learn that our brother bee-keepers across the water have had an exceptionally poor honey season this year. In the *British Bee Journal* of July 8, page 302, we find the following:

> During an experience of over forty years we do not recollect a season more unfavorable to the bee-keeper than the present. Summers, in which rain fell on almost every day, interspersed with fitful gleams of sunshine, indeed almost honeyless seasons, wherein it was impossible for the bees to store a surplus, and scarcely to live from hand to mouth, we do remember; but a season so sunless, with prevailing cold north and east winds, blowing almost continuously from November up to the 21st of June, we can not call to mind.
>
> The results to many apiarists, especially to the uninitiated, have been most disastrous.

Perhaps this state of affairs in England will have a very beneficial effect upon *our* honey-trade.

"THE PROOF OF THE PUDDING IS IN THE EATING."

Doolittle, in the *A. B. J.* of July 21, says:

> My plans are often called expensive, and my hive and fixtures complicated; but I believe there is as little labor and cash outlay by my plan of producing $1000 worth of comb honey as by any other plan in existence. As proof, I will say that from less than 50 colonies of bees (spring count) I have cleared over $1000 each year for the past 13 years, taken as an average. I have not hired 13 days' labor in that time in the apiary, nor had any apprentices or students to do the work for me, although I have had many applications from those who wished to spend a season with me. Besides my labor with the bees, I take care of my garden and a small farm (29 acres); have charge of my father's estate; run my own shop and steam-engine, sawing sections, hives, honey-crates, etc., for myself and neighbors; write for seven different papers, and answer a host of correspondence.
>
> The old saying is, "The proof of the pudding is in the eating," and so I now say, as I have said before in these columns, that all I have to recommend the plans I use is the success attained by them.

Does this not in part answer the wail of a few, "Bees don't pay"? The old saying, "What man has done man can do," applies right here. It may be there is something in the locality; but certainly a great deal rests with the man.

BEES AND BEE-KEEPING, BY FRANK CHESHIRE.

We are in receipt of Volume I. of this work, recently noticed by Prof. Cook. So far as the natural history of the honey-bee is concerned, this book in many respects is far in advance of any thing that has ever before appeared in print; in fact, I am astonished and pleased to find that we have, in any quarter of the globe, a microscopist who has gone into this subject so thoroughly as Frank Cheshire. The typographical appearance of the work is also simply a wonder; and the engravings, in beauty and excellence, are superior to any thing it has ever before been my fortune to meet anywhere in the whole realm of scientific knowledge. At the present writing I have not been able to read the book so thoroughly as I mean to do. It is, without doubt, a wonderful addition to our fund of knowledge in regard to the structure of the bee. Very likely the book contains errors, for to err is but human. The life-sized pictures of a full-grown bee are far in advance of any thing that has ever been accomplished heretofore, and we can only congratulate friend Cheshire on having been able to procure the assistance of such skillful artisans to bring his work before the world. The price of the book is $2.50—perhaps twice as much as books of a similar size cost in our country; but the beautiful engravings alone ought to be sufficient to induce any one to pronounce the book cheap at $2.50. We can mail it at that price.

MR. THOMAS HORN.

Just after our last issue went to press, the following note to Mr. Horn's customers came to hand:

> TO MY CUSTOMERS WHO ARE READERS OF GLEANINGS.
>
> On the 20th of July I will have filled all orders now on my books for bees and nuclei; and by the 25th, for queens; so if you have ordered any goods that you have not received, please let me hear from you at once, and oblige yours truly,
>
> Sherburne, N. Y., July 12, 1886. THOMAS HORN.

Very good, friend Horn; and we sincerely trust that by the time this reaches our readers there will not be one who can say his bees, queens, or *money* has not been received. If there are any such, however, they will please write directly to Mr. Horn. And I would suggest that they also state what will make every thing satisfactory, if it is not already so. If Mr. Horn does not respond promptly, then (but not before) please write us. Mr. Horn has sent us a very pretty photograph of his apiary, showing that he has a large number of hives employed in his business. He also states that he has filled over 500 orders this season, and that less than two per cent have made any complaint of dissatisfaction.

GOODS AT A REDUCTION OF 25% FOR FAIRS.

To those of our friends who desire to exhibit our goods at their county or State fairs this season, and distribute our price lists to those interested in bee-keeping, we will offer the following inducement: You may deduct 25% from the retail price of any or all of the following-named articles in our price list, providing you state in your order, in good faith, that the goods are to be on exhibit at your fair:

One saw-table for hive-making;
One dovetailing table;
One cutter-head and table;
One V-groove section machine (only 20 per cent off this);
One comb-fdn. machine, 10, 12, or 14 inch;
Clark's, Parker's, and Gray's fdn. fasteners, in any quantity;
One honey-extractor, any size;
One uncapping-can;
Metal corners, in any quantity;
50 brood-frames, either all-wood or metal-cornered, in flat, wired, or unwired;
Smith fountain pump or sprinkler;
One of each or any style of hives given in our catalogue, put up or in the flat;
One of each or any style of retailing cases;
One pair of square honey-cans in a box;
One honey-knife, each or any style;
One lamp nursery;
One sheet perforated zinc, or sample honey-board;
One box of 500 sections, 1-piece V-groove, 4¼ x 4¼;
Smokers in any quantity;
Bee-veils, one of each kind;
Wax-extractors, one of each or any one.

We will also let you have all the A B C's you want to sell, @ 40% discount; the more you sell, the better; but you must not sell them below our retail price unless you sell more than one at one sale.

$2.50 CHEAP $2.50

I will sell three-frame (Simp. size) nucleus colonies, all straight worker-comb, well-filled with brood and honey, 1 pound of Italian bees, and nice tested Italian queen, for only $2.50. Now, friends, I guarantee these colonies to be first-class in every respect. Fifty colonies ready now. A fine lot of untested queens at 75 cts.; $4.00 per ½ doz., and tested at $1.00; $5 50 per ½ doz. Safe arrival and satisfaction guaranteed. **F. W. MOATS,**
14d The Bend, Defiance Co., Ohio.

NOW READY, ITALIAN QUEENS.

1 queen. $1.00; 2, $1.80; 3, $2.50; 5, $3.75. Bees by the pound, nucleus. and colony. 13-15db

Foundation-Mill For Sale.

One ten-inch Root comb-mill, second hand. The mill has, however, been completely fitted up, painted, and varnished, and is, to all appearances, both in looks and quality of work, equal to a new one. Price $15.00. The list price of a new mill of this kind is $20.00. **A. I. ROOT, Medina, O.**

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or $2.00 per annum, when given once a month, or $4.00 per year if given in *every* issue.

$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or $2.00 per year.

Those whose names appear below agree to furnish Italian queens for $1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for $1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey.*—The honey market is almost devoid of interest, more particularly in comb honey. We find quite a large stock being carried over in dealers' hands; although our stock is light, what we have is dark and off grades, and will be in good position for the coming crop. It is difficult to tell what prices will be on the new crop; but from reports received from nearly all sections of the country, we think prices will be low. Present quotations as follows:

Fancy white comb, 1-lb. sections	10@12
" " " 2-lb. "	8@10
" buckwheat 1 and 2-lb. sections	5@8
Extracted, white clover	5c
" California	4½@5
" Southern per gallon	45@55

Beeswax, 23@25. **McCAUL & HILDRETH BROS.,**
July 10, 1886. 34 Hudson Street, Cor. Duane St.
New York City.

KANSAS CITY.—*Honey.*—The receipts of new honey are good, and very fine. The demand is good, and stock in store is light of one-pound frames.

One-pound frame, white clover,	13@14
One " " dark	11@12
Two " " white clover	11@15
" " " dark	8@10
" " " California white	10@11
" " " dark	8@9

Extracted white clover, 5@6; dark, 3@4. California white, 4½@5. Dark, 3½@4. *Beeswax*, 20@22.
July 22, 1886. **CLEMONS, CLOON & CO.,**
Cor. 4th and Walnut St's, Kansas City, Mo.

MILWAUKEE.—*Honey.*—The market is fairly supplied with honey, and trade is dull, and prices depressed: outlook for a large production, and already some is being peddled about the city by the raisers themselves, demoralizing the prices, which should not be done. We will quote choice white, in 1-lb, sections, 14@15; the same in 2-lb. sections, 13@15; extracted, in bbls. and kegs, white, 5@7; in tin cans, white, 6@8; extracted, dark, in bbls. and kegs, 4@6. *Beeswax*, 25. **A. V. BISHOP,**
July 23, 1886. 142 W. Water St., Milwaukee, Wis.

CINCINNATI.—*Honey.*—There is no new feature in the market. Demand from manufacturers is still dull, but somewhat improved. The honey harvest is below a medium crop in Ohio, Indiana, and Kentucky; but no improvement in prices need be expected, judging by present indications.—Prices for extracted honey range from 3½@8c on arrival. No arrivals yet of new comb honey, and prices nominal. *Beeswax.*—This is in fair jobbing demand, and arrivals are good. It brings 18@22 cts. for good to choice yellow on arrival. **CHAS. F. MUTH & SON,**
S. E. Cor. Freeman and Central Avenues,
July 19, 1886. Cincinnati, Ohio.

CHICAGO.—*Honey.*—Honey is coming on the market very freely, and is of good quality. At present there is not any demand, so that prices are nominal. Any offer at 12@13c would be accepted, yet 14c is being asked. Extracted, without change.
Beeswax, 25. **R. A. BURNETT,**
July 21, 1886. 161 So. Water St., Chicago Ill.

DETROIT.—*Honey.*—Comb honey in 1-lb. sections is bringing 11@13c per lb., and the market is well supplied. Extracted is dull, and very few sales, bringing 8@9 cts. *Beeswax* is in good demand, but a little lower for average wax. We are paying 23c. **M. H. HUNT,**
July 21, 1886. Bell Branch, Mich.

CLEVELAND.—*Honey.*—The market at present is rather dull; prices, however, are well maintained. Choice new 1-lb. sections of white are selling at 14c.; second quality, 12@13. Extracted not salable.
Beeswax, 22@25. **A. C. KENDEL.**
July 26, 1886. 115 Ontario St., Cleveland, Ohio.

NEW YORK.—*Honey.*—There is no change in the market of honey since our last report, about two weeks ago. **THURBER, WHYLAND & CO.,**
July 12, 1886. Reade and Hudson Sts.,
New York, N. Y.

BOSTON.—*Honey.*—There is no change in prices of honey. Sales are very light. **BLAKE & RIPLEY,**
July 12, 1886. 57 Chatham St., Boston, Mass.

FOR SALE.—3000 lbs. of perfectly ripened white-clover extracted honey, in 55-lb. iron-jacket tin cans at 7c per lb., and Mr. A. I. Root's price of can.
MRS. NELLIE M. OLSEN,
Nashotah, Waukesha Co., Wis.

FOR SALE.—1000 lbs. white comb honey in sections, put on board cars here for 14c per lb.
WM. WITHROW, Paint Valley, Holmes Co., Ohio.

FOR SALE.—2000 lbs. of white-clover and basswood honey in 1-lb. sections, and 3500 lbs. of extracted, put up in 25-gal. barrels. What can you pay for it, delivered here on board of cars? If you would like a sample, I can send you one.
H. B. MORRIESOON, Fayette, Fayette Co., Iowa.

FOR SALE.—A No. 1 extracted honey, from clover and basswood, in the following packages—package free, delivered on board cars in Newton: 3 one-half bbls. @6½c per lb.; 2 10 gallon kegs @ 7c per lb. Also about 150 gallons in open bbls. Satisfaction guaranteed. **SAMUEL LISTER**, Newton, Iowa.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

A few black queens, at 15 cents.
JNO. C. CAPEHART, St. Albans, W. Va.

Mismated queens, reared from select tested Italian queens. I have 20 now, which will go for 40 cts. apiece. Prompt shipment and safe arrival guaranteed. **S. H. COLWICK**, Norse, Bosque Co., Texas.

I shall have 8 hybrid queens in August, at 25 cts. each; 5 for $1.00. I insure safe delivery—all young queens. **BEN. J. COLE,**
Marietta, Washington Co., Ohio.

I shall have a few black and hybrid queens in August, to sell at 20 and 35 cents. Safe arrival guaranteed. **LUTHER W. GRAY**, Orlando, Fla.

I have 14 mismated queens which I want to sell. Price, three 30-cent ones and eleven 50-cent ones.
R. H. BAILEY, Ausable Forks, N. Y.

I have a few black and hybrid queens for sale, at 25 cts. each; also a few queens that produce mostly three-banded bees, at 50 cts. each. I warrant all to be good prolific queens. **L. W. VANKIRK,**
P. O. Box 178. Washington, Pa.

I have a few fine hybrid queens for sale at 40 cts. each. **LEE SPAHR**, Xenia, Ohio.

I have some hybrid queens in the neighborhood that I will sell at 25 cts., yellow and prolific.
C. C. KIRKMAN, Coxville, Pitt Co., N. C.

I have 20 prolific hybrid queens to dispose of at 25 cts. each, rather than kill them.
W. A. SANDERS, Oak Bower, Hart Co., Ga.

I have several young hybrid qoeens to dispose of. Will mail at 35 cts. each, or 3 for $1.00.
N. ADAMS, Sorrento, Orange Co., Fla.

I am Italianizing, and will have over 30 queens which I will sell for 10 cts., and a provisioned queen-cage each. **W. J. FINCH, JR.**, Chesterfield, Ill.

One dozen hybrid queens for sale from Aug. 1st to 15th, for 30 cts. each, or four for $1.00. Ready now. **GEO. P. KIME**, Evansburgh, Cosh. Co., O.

I have some Italian hybrid queens that I will mail at 30c each, and guarantee safe arrival.
N. A. KNAPP, Rochester, Lorain Co., Ohio.

EXPLANATION: To the many who have sent to us for our catalogue, and have not received one, we would explain that the demand has been greater than we could supply, but we will send one of our next annual edition to all such as soon as issued. **WATTS BROS.**
Murray, Clearfield Co., Pa. 15d

EXCHANGE DEPARTMENT.

WANTED.—To exchange 20,000 strawberry-plants, Crescent Seedling, Cumberland Triumph, Sharpless, and Glendale, 75 cts. per 100; $4.00 per 1000, for bees, foundation, or improved poultry.
10tfdb W. J. HESSER, Plattsmouth, Neb.

WANTED. — A partner to take half-interest in an Apiary, with a little capital. Address
LOUIS WERNER, Edwardsville, Ill.

FOR SALE.—Pasteboard boxes for inclosing section honey. The best out! Improved over last year. Thousands sold! Price, 1-lb. size, $6.00; 2-lb., $8.00 per 1000. One sample, 5c. 14-oz. square glass jars, $5.00 per gross; 1½ gross in case. Fine assortment of honey labels. Catalogue free.
14-17db A. O. CRAWFORD, S. Weymouth, Mass.

WANTED.—To exchange bees or queens for foot-power saw. Will sell fine tested queens for $1 each; untested, 70 cts. each, either Syrian or Italians. ISRAEL GOOD, Sparta, Tenn.

WANTED.—To exchange Italian queens for alsike clover seed. J. T. VAN PETTEN, Linn, Kan.

WANTED.—To exchange best drone-traps made for one or more extractors, Simplicity frame. Send for circular.
15tfdb J. A. BATCHELDER, Keene, N. H.

WANTED.—To exchange for comb or extracted honey, cash or offers, 15,000 pot-grown strawberry plants of the best varieties; also game cocks. Can give best reference. GEO. M. WERTZ,
15tfdb Johnstown, Cambria Co., Pa.

FOR SALE, or will exchange for 20 two-story Simplicity hives, complete, in flat, golden Italian queens. Price, mismated, 50 cts.; untested, 75 cts. Tested, $1.50; best select tested, one year old, $2.50. Safe arrival and satisfaction guaranteed. Reference, Bank of Princeton, and L. Goodwyn, P. M., Frenchville, W. Va. L. L. HEARN,
Frenchville, W. Va.

WANTED.—Situation by young man who understands bee-keeping and hive-making; is handy generally, and willing to be generally useful. $16 per month south (Texas preferred), $18 north, if job is steady and pay sure; 6 years' experience; good reference; present engagement expires Nov. 10th. Write at once. A. DURWARD, Merrimac, Wis.

WILL sell for cash or give in exchange for good horse, 25 colonies of black, hybrid, and Italian bees, in S. hives, on 5 frames brood each, at $5.50, $6.00, and $6.50 respectively. Will ship long as weather permits. 16-21db J. A. KIME, Fairfield, Adams Co., Pa.

WANTED.—To exchange for honey, or offers, three chaff hives, taking 10x15 frames; 40 brood-frames; 400 1-lb. boxes; two hives; bees; drone-trap; section-cases, etc. OTTO LESTINA.
16d Derby, New Haven Co., Conn.

FOR SALE.—A two-story brick house, with five lots, good barn, ice-house with cooling-room, bee-house, honey-house, wood-house, etc. Grapes, berries, apples, and cherries on the place; in small town, location suitable for bee or chicken business. Will sell cheap for cash, or exchange.
15-18db ANABEL RONALD, Grand View, Iowa.

WANTED.—To exchange Wyandotte fowls for Italian bees. W. H. OSBORNE, Chardon, O.

FOR SALE.—20 tested Italian queens at $1.00 each, or will exchange for comb fdn., or 1-lb. one-piece sections, 4¼x4¼. Address
16 JOS. GRIFFIN, Rio, Alb. Co., Va.

WANTED.—To exchange bees by the pound, nucleus, or full swarm, for any thing I can use in the apiary; or a male Poland China pig; or for cash. Write for prices and make offers.
16d LUTHER PURDY, Killbuck, Holmes Co., O.

WANTED.—To exchange one 3-oz. silver open-face watch, for best offer of comb or extracted honey, or offers. CHAS. L. HILL, Dennison, O.
16tfdb

WANTED. — To exchange Italian bees, on 10 frames, L. size, drawn from fdn., for a 48 or 51 inch *Star* bicycle.
16d C. H. SMITH, Pittsfield, Mass. Box 908.

Black and Hybrid Queens For Sale.

A few hybrid queens for sale, at 25 cents each.
O. H. HYATT, Shenandoah, Iowa.

I have about 3 black and 10 or 12 hybrid queens to sell at 20 cts. for black, and 30 for hybrid, or 4 for $1.00; all young and prolific. Some of them are daughters of hybrid queens, mated with pure Italian drones.
LUTHER PURDY, Killbuck, Holmes Co., O.

Four fine Italian queens in exchange for cockerels of any good breed chickens.
CHAS. L. HILL, Dennison, Ohio.

I have a few mismated Italian queens to dispose of at 35 cts. each, or 3 for $1.00. These queens are almost pure.
GEO. W. BECKHAM, Pleasant Hill, Lan. Co., S. C.

Wishing to Italianize my apiary, I have one hundred black and mismated queens for sale; mismated, 40 cts., and blacks, 15 cts. Address
W. G. HAYEN, Pleasant Mound, Bond Co., Ill.

Black and hybrid queens for sale now. Can ship upon receipt of order, and will guarantee safe arrival. Prices, black, 20 cts.; hybrid, 35 cts.
16-17-18 J. A. BUCKLEW, Clarks, Coshocton Co., O.

I have for sale 2 first-class hybrid queens at 40 cts. each. W. J. HILLMAN, Green River, Vt.

I have 4 hybrid queens, for which I will take 25 cts. apiece and guarantee safe delivery.
D. M. WEYBRIGHT, New Paris, Elkhart Co., Ind.

I have 75 black and hybrid queens for sale at 25 cents each; or I will exchange for strawberry-plants, 4 queens for 100 plants.
THOMAS GEDYE, La Salle, La Salle Co., Ill.

Mismated queens, reared from select tested albino and bright Italian queens, now over 5 weeks laying, at 50 cts. each. Shipped by return mail.
DR. JOHN M. PRICE, Tampa, Hillsboro Co., Fla.

HELP! HELP! HELP!

Me develop my honey-trade in Philadelphia by consigning me your honey. Those I have sold for, express satisfaction.

THE WAX QUESTION.

HOW MANY POUNDS OF HONEY DOES A POUND OF WAX ACTUALLY COST US?

THE beautiful agreement of authorities, that it requires twenty pounds of honey to make one pound of wax, is not, I believe, owing to a concurrence of experiments. The experiments often indicate much more than that —100 to 1 sometimes. The authorities concur that 20 to 1 is about all we can be got to believe, and so state it at that. The fact seems to be, that no experiment of this kind is worth a rye straw unless the bees have their entire liberty, and are at work on natural supplies in a perfectly natural way. It is difficult to grant them this much, and at the same time weigh things as accurately as exact science relishes; but there is no help for it. Truthful approximations are better than exact figures that begin and end in utter falsehood.

That the prevalent doctrine is an utter falsehood, might be readily inferred from the way bees treat wax after they get it secreted. Much of it is at times dropped to the bottom of the hive, and blown out as worthless litter. The scales in which it is formed seem quickly to get a little dry and stiff, and they prefer to secrete fresh ones. Now, the bee is, by nature, a miser—and 20 to 1 is somewhere near the present ratio of silver to gold. When you can find a miser who will pinch the silver coins till they squeak, and at the same time throw the gold coins on the floor, and sweep them out into the street, then you may look for a bee that will be equally wasteful of his resources. True, the bee can not reason about the matter; but the developments of nature, and the *ultimate* conclusions of reason are usually in accord. That is, nature has already reached the point where reason, after floundering about, and making all the mistakes possible, will finally come to rest. We can deduce the same thing again by this little simple experiment: Expose a section of nice comb-honey. The bees, if not otherwise engaged, will carry the honey away with an eagerness that amounts almost to frenzy. But how about the delicate comb, worth twenty times as much as the honey, weight for weight? The bees are perfectly capable of carrying home the comb, and have been known to do so as an occasional eccentricity; but ordinarily they can not be made to take it.

Now for the experiment which you requested me to write up: July 4th, 1885, a good but rather small prime swarm of bees was hived on a delicate scale which will weigh ounces, in order that their income and wax product might be estimated as closely as possible. The swarm weighed just three ounces less than four pounds, and was hived about sundown. During the night they decreased in weight two ounces. The average decrease in weight at night during the experiment was about twice this, or four ounces per night.

The plan of the experiment was to let them work undisturbed four days (as long as they could without eggs hatching), and then to cut out the products of their labor, weigh the amount cut out, render the wax, and weigh that. From these data a ratio can be approximated. After this they were to be undisturbed four days more, and then be fleeced again. Then a third trial of the same period was to be put upon them, after which the experiment was to be closed. The colony was weighed every morning and night.

This plan leaves several things not quite positive. How about the honey they had in their sacs to commence with? A four-pound swarm *may* have over a pound of honey. At other times they have only a very few ounces. This swarm evidently had a small supply, as they weighed seven ounces more after the first cutting was made than they did the morning after hiving. At any rate, the honey they had in their sacs at the close of the experiment offsets what they had to begin with; and I make an allowance in the separate trials for the change in the weight of the bees. Did they have any wax already secreted? I think not. The evidence is that they did better the second trial than they did the first. I make no attempt to estimate the daily mortality. The *usual* loss of a colony for 12 days, according to the authorities, should be about one-fourth of the original weight; but the fact that this colony weighed the same at the close that it did in the beginning shows that the mortality was not a pound of bees, nor any thing like it. Perhaps mortality does not become heavy until there is brood to feed. Some honey gathered at morn is eaten and dissipated before night, and so escapes the scale, while the wax product of it remains. To balance this on the other hand, all these pounds and ounces are pounds and ounces of rather raw nectar, not of ripe honey. As to the amount of honey used as food at night, a colony rearing brood rapidly uses seven ounces per night; an active colony not rearing much brood, from one to three ounces; a colony in a quiescent state, only a fraction of an ounce. During this experiment there was an average loss by night of 4 ounces. I have assumed that one-half of this was waste caused by vitality and muscular action, and one half the chemical waste of elaborating wax.

FIRST TRIAL.

First day's gathering of honey and pollen, 6 oz.; 2d, 13 oz.; 3d, 8 oz.; 4th, 16 oz; total, 43 oz. Subtract from this—Honey and pollen cut out, 19 oz. Four days' food, 8 oz.; increase of honey in sacs, 7 oz.; total for subtraction, 34 oz.

Remainder, or amount spent in secreting wax, 9 oz. Weight of wax, 2 oz. 10 dr. Honey spent in making 1 oz. of wax, 3½ oz., nearly.

SECOND TRIAL.

First day's gathering of honey and pollen, 0; 2d, 12 oz.; 3d, 11 oz.; 4th, 25 oz.; total, 48 oz. Add also 6 oz. decrease of the amount in their honey-sacs. Corrected total, 54 oz.

Subtract from this—Honey and pollen cut out, 35 oz.; 4 days' food, 8 oz. Total for subtraction, 43 oz. Remainder, or amount spent in secreting wax, 11 oz.

Weight of wax, 4 oz. Honey spent in making 1 oz. of wax, 2¾ oz.

THIRD TRIAL.

First day's gathering of honey and pollen, 5 oz.; 2d, 5 oz.; 3d, 22 oz.; 4th, 16 oz.; total, 48 oz. Add also 1 oz. decrease of the amount in their honey-sacs. Corrected total, 49 oz.

Subtract from this—Honey and pollen cut out, 33 oz.; four days' food, 8 oz. Total for subtraction, 41 oz.

Remainder, or amount used in secreting wax, 8 oz.

Weight of wax, 3¼ oz. Honey spent in making 1 oz. of wax, 2½ oz., nearly.

It will be seen that the average of the three trials gives very nearly the ratio of three to one. Perhaps a less mincing summary would hit the average reader more forcibly. Here are bees that made almost ten ounces of wax. *The books say that they must have had over twelve pounds of honey to do it with, while in fact they were allowed to keep just three pounds and a quarter.* Quite a discrepancy, is it not?

It does not follow that we are going to produce big crops of wax at a profit right away. There is another difficulty to surmount. I have twice run a good colony the whole season for wax, and so I have a right to know. After 10 or 15 days of wax-secreting, bees seem unable to secrete much more; and how to get the new supply of young bees promptly, without stopping the wax secretion of the first set, is the problem. E. E. HASTY.

Richards, O., July 6, 1886.

Friend Hasty, the facts you give us are astonishing, to me at least; at any rate, your experiment is certainly a very valuable one. It appears to be all right, but perhaps there may be something you have overlooked in it, after all. I am very glad indeed to be able to submit it to the keen intelligence of the readers of GLEANINGS. How is it, friends? has Hasty made any big mistake in this matter? You say you ran a good colony the whole season for wax; why do you not tell us right here how much wax you got? I have for some time felt that there must be a mistake about the 20 lbs. of honey for one of wax, because of the quantity of wax single colonies have sometimes furnished. Now, then, who will tell us how we shall go to work to produce wax at a profit? Can we do it by feeding sugar? I have noticed the lavish way in which bees sometimes seem to kick around their scales of wax. It has, however, been, as a general thing, after I had been feeding them and got them a little out of their natural and normal condition.

DESCRIPTION OF BEES, QUALITY OF QUEENS, ETC.

FRIEND DOOLITTLE'S EXPERIENCE IN TESTING THE DIFFERENT RACES.

I HAVE been besieged of late by some parties in Pennsylvania to write an article for GLEANINGS on the qualities of different races of bees, color of queens, and the quality of queens reared by natural swarming as compared with those raised "artificially," as it is termed. I wrote the parties that, as I was a queen-breeder, I did not think friend Root would care for my views on these subjects for GLEANINGS, for it might look as if I had an "ax to grind;" but this does not pacify; an article they must have, so I have consented to try a rather difficult task, for I know that few if any will agree with me on all the points. However, I shall try to give an impartial article, telling just what I believe to be the truth. First, then, we have the

QUALITIES OF THE DIFFERENT RACES.

The black, or German bee, probably all are familiar with. All the really good qualities I know of them is their readiness to enter the sections and build comb, and smooth white capping of the honey in the same. Their poor qualities, as I find them, is their inclination to rob, and willingness to be robbed; their running from the combs, and out of the hive, unless handled very carefully; do not resist the wax-moth; are poor honey-gatherers, except in times of plenty; inclined to sting with little provocation, and do not do work in a business-like way. This last particular I do not know that I ever saw mentioned; and by it I mean that they live only from hand to mouth, as it were, calculating only a day or so in advance. They go into the sections to work, and build comb only so long as honey comes in plentifully. The least slack stops comb-building, only that the cells are lengthened on that already built, so that I have frequently found sections one-fourth full of comb, and that one-fourth lengthened out, filled, and capped over without being attached to the sections except at the top. I never saw any thing of the kind with any other race of bees, for they all start and build the sections full of comb as if they calculated to do something business-like. If another yield of honey comes in a few days, these bees start the comb down a little further, when it is again stubbed off if the flow slackens, and again and again do the same thing until I have counted as many as five times in a single section where they have started and stopped, making the face side of the comb resemble a washboard. It has been claimed that there is a difference in these bees, some saying that there is a large *brown* bee of superior merit; others claim great things for their *gray* bees, both of which are said to be a great way ahead of the *little black* bee; but I wish to say, that, after getting queens from several claiming to have these superior strains, and placing them beside the "little black bee" our forefathers used to have, there is not a bit of difference in them so far as I can see, or any of my bee-keeping friends to whom I have shown them. Well, I must "curtail" or I shall not get along very fast.

I have thoroughly tried the Syrians; and for this locality I consider them the poorest of all the bees yet brought to this country. The two great faults which make them thus are, first, not breeding when they should breed, and then breeding beyond measure when they ought to breed but little, which results in few laborers in the field in the honey-harvest, and countless numbers of consumers after the harvest is past, to eat up all that the few gathered. Consequence, *no profit*. Second, the workers begin to lay eggs as soon as the queen leaves the hive, whether by swarming or otherwise, so that the combs are filled with a multitude of dwarf-drones, to the disadvantage of bees, combs, and owner. Fertile workers are always present with these bees. At times they sting fearfully; at other times they are nearly as peaceable as Italians. However, they will not venture an attack unless the hive is disturbed, as do the black bees. A colony of Syrian or Cyprian bees will let me stand an hour at a time right in front of their entrance, turning out for me, and not one offering to sting; while in less than two minutes a black colony will resent such impudence to the score of hundreds of stings, if you don't leave. The Cyprians, I dislike to part with, for they are really a good bee in all points but one; but that *one point* is altogether too sharp for me. Of all the bees to sting when provoked, this bee "beats all." My flesh fairly crawls as I write, to think how I have been stung by them. In opening a hive, smoke does no good, while the least mishap will, without warning, send hundreds of hissing, angry, biting, stinging bees all over you. They also have "a touch" of the laying-worker nuisance, but nothing like as bad as the Syrian. I still have a colony of Cyprians, which I expect to brimstone this fall. I have twice tried to find the queen this season, to supersede her, but have been stung so that I gave it up. Perhaps brimstone won't kill them; but I'll try it and see.

The Carniolans, so far as I have tried them, are a rather mixed race or only a very peaceable strain of the black bee. My trials of them agree exactly with what friends Root have said of them in late numbers of GLEANINGS. Some of the queens produce a hybrid progeny, while others give nothing but black bees. As to the "steel blue" color claimed for them, I will say that the same will be seen on a lot of black bees, just hatched, if held so the light strikes them just right. As far as I am concerned, I have no use for them. It is hardly necessary for me to say that the Italians (home bred) are my choice, and especially as I find them now, after we have passed through almost the poorest honey season we have ever had, at work on red clover, and storing honey from it in sections, while hybrids and other bees are scarcely getting a living. This one quality alone, of home-bred Italians working on red clover, would give them the preference over the other races, with me, had they not many other redeeming qualities besides. I can not help thinking that Ernest is mistaken in thinking that the superior working qualities he sees in imported stock is wholly due to the fact that they *are* imported. I believe that it is in the crossing which gives the great vigor. I have more imported stock in my yard than ever before; and I find that, from my best improved bees (done by judicious crossing) I have, and am likely to obtain, double the honey I shall from the imported. I also find that daughters of imported stock, crossed with my stock, stand much ahead of their mothers as to the gathering qualities of their worker progeny. This is the result given in this, the poorest of all seasons (with me) for 14 years.

Well, this article is already too long, and I have hardly got half through. With the editor's permission I will conclude it in the issue for Sept. 15.

Borodino, N. Y., July 31, 1886. G. M. DOOLITTLE.

By all means, friend D., give us the rest of your very valuable communication. I do not know how you could think we shouldn't care for your views on this most important subject. I believe our experience agrees with all you say, unless it be in regard to the progeny of our imported queens; and as honey-raising is not a specialty with us, you may be the nearest right. I am quite sure that a great improvement could be made by persistently rearing queens in colonies that give us the largest honey-yields.

"BEES AND BEE-KEEPING," AGAIN.

WHAT IS SALIVA AND ITS FUNCTIONS?

I HAVE read Prof. Cook's review of "Bees and Bee-Keeping" with pleasure, and I feel sure every reader of GLEANINGS will think more highly of him for the good-natured way in which, as the editor says, he "stands fire." It has been said, that Mr. Cheshire's criticisms show an unkind spirit toward Prof. Cook. I find he is quite as severe in criticising the works of other authors; and I think in no case is he too much so, provided he is correct as to his facts. If, on closer investigation, it be found that he is in error, it will be in order for those authors to handle him as vigorously as was recently done by the editor of the *British Bee Journal* on the subject of bacteria. There does not seem to be as much "gush" and "slopping over" amongst writers in the old country as we sometimes see on this side of the water.

Referring to the similarity of the digestive process in all animals, on page 58 of "Bees and Bee-Keeping," Mr. Cheshire says: "During the process of chewing, or mastication, glands, of which we, like the bees, have three pairs, pour into the mouth saliva, whose principal office is to chemically change some parts of our food, and notably starch, which, under its action, begins to be formed into sugar, one of the most soluble bodies furnished by the plant world."

Regarding this statement, Prof. Cook remarks as follows: "Here Mr. Cheshire makes a strange error in the statement that our saliva is wholly a digestive liquid, that it changes starch into sugar. It is well established, that our saliva is almost wholly mechanical in its function, and that the pancreatic juice digests the starch." Prof. Cook probably follows Dr. J. C. Dalton, Jr., who says: "The function of saliva is altogether a physical one. Its action is simply to moisten the food and facilitate its mastication, as well as to lubricate the triturated mass, and assist its passage down the œsophagus." Dr. Dalton refers to the investigations of leading French and German authors in support of his view; but their observations were made on the masticated food of some of the lower animals, in which cases no glucose was found. The results of these observations do not necessarily prove that Dr. Dalton is correct; because later investigations have shown that, "whilst the saliva of man and some few animals possesses the remarkable diastatic ferment, it is absent from the saliva of a majority of animals."

On the other hand, on page 141 of his Physiology, Prof. Huxley says: "The secretion of these salivary glands, mixed with that of the small glands of the mouth, constitute *saliva*—a fluid which, though thin and watery, contains a small quantity of animal matter called *ptyalin*, which has certain very peculiar properties. It does not act on proteid food-stuffs, nor upon fats; but if mixed with starch, and kept at a moderately warm temperature, it turns the starch into grape sugar. The importance of this operation becomes apparent when one reflects that starch is insoluble, and therefore, as such, is useless as a nutriment; while sugar is highly soluble, and readily oxidizable." And on page 154 he says: "The conversion of starch into sugar, which seems to be suspended wholly, or partially, so long as the food remains in the stomach, on account of the acidity of the chyme, is resumed as soon as the latter is neutralized, the pancreatic and intestine juices operating powerfully in this direction."

In his article on "Nutrition," in *Encyc. Brit.*, published in 1884, Prof. Gamgee says: "The process of mastication, besides triturating the food and mixing it with the alkaline saliva, permits it to become raised nearly to the body temperature, in which condition the dextrine and the starches readily fall a prey to the ptyalin, and begin to be converted into dextrine and maltose. This change is very rapidly effected—it begins instantly, if the starch is already boiled, so that, unless the food is "boiled," a considerable quantity of soluble dextrine and sugar is formed before the bolus is swallowed."

From the foregoing it will be seen that, although he disagrees with Dr. Dalton, Mr. Cheshire is in accord with some of the latest and best authorities of the day. S. CORNEIL.

Lindsay, Ont., Can., July 26, 1886.

Thank you, friend C.; but when doctors disagree in such matters, who shall decide? Unless some special reason shall make it very important to know the exact truth, I can not see why it matters very much after all, as to who is right and who is wrong.

A SUGGESTION IN REGARD TO HANDLING FOUL BROOD.

ALSO SOMETHING ABOUT THE NAMELESS BEE-DISEASE.

IN GLEANINGS for Aug. 1, 1886, page 610, you describe what is evidently foul brood. In burning the combs you did all right; but why starve the bees, when there is a better way? In my experience in bee-keeping of over 21 years, I have had to deal with foul brood four different times, either in my own yard or in the yards of some of my friends. I condemn the practice of starving the bees, as it makes them almost worthless after such treatment for future comb-building. I believe it is well understood, that bees must be *fat* to build comb to any extent. Put them in a box, and feed them; make them build comb for three or four days; feed them well; keep them fat; then put them on other combs or foundation, and they will be in condition to build combs and rear brood. Don't be afraid. The comb-building in the box uses up all the honey the bees may have carried with them from the foul-brood combs.

THAT BEE-DISEASE THAT HAS NO NAME.

Let me call your attention to GLEANINGS for October 1, 1885, pages 658 and 677. For several years, at times, I have seen those nervous, shiny-looking bees (made shiny by the other bees worrying them trying to get them out of the hive), but I have never known of any loss of whole colonies until the present season. In this locality the disease is quite prevalent, in some instances causing the loss of the entire swarm. Changing the queen does not stop the complaint. Sometimes a swarm afflicted with the disease will recover in a few days, and remain well, while others, after recovering the first time, will again be taken down with the same disease. I have used salt, a small handful, placed at the entrance of each hive, where the breath of the bees at night dissolves a portion of the salt, which the bees seem to like. With some swarms it seems to help them, curing them in a few days completely, while with others it seems to have no effect. I have in some instances seen from a pint to a quart of bees thrown out in 24 hours.

QUESTION.

What effect, if any, does this disease have on a swarm, that, having once had it, survives the winter? Does it follow that they will have the same disease the second year? Will some one who has had experience with this disease answer?

So far as my observation goes, the *brood* is not affected by the disease—at least it looks healthy.

QUESTION.

Is there not something which, if fed the bees, will be a positive cure? Is it not a nerve disease? Certainly the bees appear very nervous.

What of the honey season? So far as I know, there will not be one-fourth of an ordinary crop.

Fabius, N. Y., Aug. 2, 1886. H. D. MASON.

Friend M., I think very likely you are right about making bees build comb or build out sheets of foundation, instead of starving them. With us we can not afford to risk any thing on experiments. At present writing, Aug. 4, but one more colony has been found showing any trace of the disease.—In regard to the "nameless bee-disease," as it has been called, we can not answer your questions. There may possibly be some specific, if we knew just what it is; but I believe medical men tell us there are very few specifics that are certain in all cases. I have never noticed it in winter time, but have several times seen it appear as early as April.

THE HONEY SEASON IN THE MISSISSIPPI VALLEY.

CHILLED BROOD, AND HOW TO CLEAN FROM THE COMBS.

MR. EDITOR:—What is the matter with the bee-keepers adjacent to the Mississippi River, in Mississippi, Louisiana, and Arkansas? Are they still in the business, or are they so busy handling their honey crop that we see no notice of them in any of the bee-papers? or is it that their bees have done so little that they are ashamed to make known how little they have done? I think there should be some reports from some of the sections between Memphis and New Orleans, as this section can be classed as a large honey district. The failure of the crop in this region, it seems to me, ought to have some effect in stiffening the market. A large crop from California always bears down the market somewhat, and a good deal sometimes. Likewise a full crop in the Mississippi Valley has its effect. I think it well for the condition of the crop to be known for so large a region as the Mississippi-Valley district, for the effect it will have on the general market. Although so far we have in this locality almost a failure, yet we should be glad to have it known in all the markets that such is the case, for the tendency it would have to keep prices up. It should be our aim to keep prices up as well as we can, though we may not get the benefit of them for another year. We should not be jealous of those who happen to be successful this season. If it will help to raise the price of extracted honey to tell you that the honey yield in St. Charles Parish, La., has so far been exceedingly small, I shall be glad to inform you such is the case. If the whole district of the Mississippi Valley, from Memphis down, and probably from Cairo too, has not the same report to make, "exceedingly small," please let's hear from some of the big producers, and let them give quantity and number of hives, spring count, and see if the report is not "exceedingly small" compared with other years.

I began this season with 125 hives, in fine condition. Up to June 9th I extracted 26 lbs. per hive. I have extracted only about 10 gallons since. Swarming time here begins usually about April 15th. My 125 hives were in as fine shape as any bee-keeper could wish, when all at once we had a cold spell, and the brood chilled. Two hives in particular had 13 well-filled frames of brood, and a great many had 9, 10, and 11 frames filled with brood. Every one of my strongest hives was ruined. I waited till the latter part of June for them to clean out the combs and build up again, but they would not do it; so to get any benefit at all from those hives, I took their frames all out that had dead brood in, and took them to the extracting-room and uncapped them, and, putting the frames in the extractor, I made things hum. I could not spare the good brood scattered about here and there, because that bad brood had to come out, and the good had to come with it. I then put them back in the hives, and the bees cleaned them up; but they could not clean all of them well enough, for some of the fresh brood in those cleaned combs died. Now, it wasn't foul brood, because there were no sunken caps with pinholes in them, nor did they have that stench in the hives; but I tell you the air was thick with unpleasant perfumery when I was extracting those frames. I extracted over twenty hives, and threw out over ten gallons of the rotten, slimy stuff. They were thrown back so much by the operation that many of them dwindled down; and besides having no swarms, I have reduced my stock by uniting to 117 at present, and shall, as rapidly as I can, reduce them to about 100 hives. If any of the Pelican bee-keepers can boast of the wonders of Louisiana as a honey State for 1886, I am ready to read all such reports; but I should like affidavits to accompany reports of large yields. Louisiana has yielded enough rain water this season to supply the whole Union. When this section gets dry, the ground cracks open, and is as hard as a brick; and when it rains too much the ground gets tough and gummy, like rubber or glue.

May be next year we'll get a chance to astonish you. If we do, then you'll have to have a "Louisiana" column in which to chronicle big yields; but on off years like this one up to date, the Mississippi-Valley bee-keepers are conspicuous by what they don't report. 3—C. M. HIGGINS, 125—117.

Hahnville, St. Charles Par., La., Aug. 3, 1886.

FLORIDA.

AN ADVERSE REPORT FROM OUR OLD FRIEND W. S. HART.

HERE we are, arrived at the ordinary time for our surplus honey-flow of the season to begin to check up, and yet there are not, as far as I can learn, a dozen barrels of surplus honey in this "bee-belt," as it is often called. This season has certainly been an anomaly to the bee-keepers of this part of Florida. I do not care to give a full report of the season up to date just now, but will say that bees bred up very strong in March, where there was plenty of honey in the hive to go with what little was gathered in the field. It seemed as though they would turn honey into brood to almost any extent in proportion to the amount of the former that was provided them. There was considerable swarming during the late days of March and through April, although there was but very little honey coming in. Almost all swarms had to be fed at once; and if given uncapped brood they would construct queen cells on it and cast a swarm before any eggs were laid. I never saw swarms cast before, when so little honey was coming in. Instead of the usual dry weather through April we had a good deal of rain, and the drought commenced in May, about the time that the summer rains usually commence. It continued very dry until June 18th, when we had quite a shower. Since that it has rained almost every day, and is raining now. I do not think that any one here has ever seen more water in the "flat woods" and hammocks of this "coast section" than there is at present. The dry weather in May and June prevented all of our honey-producing plants and trees that usually come in then, and give us our early surplus, from doing much more than to provide for the wants of the brood.

The mangrove crop, as before stated, having been destroyed by the unprecedented cold of last winter, our only hope for a crop of white honey was based upon the cabbage palmetto. This tree was watched with much interest, as there has been considerable discussion as to its merits as a honey-producer, some claiming that most of last year's white-honey crop came from it, while others claim that they have never had a barrel of honey from the tree, as it produces only pollen. What makes it so difficult to decide this matter is the fact that both it and the mangrove are in bloom at the same time, and the bees are hard at work upon both, and at times honey is coming in quite rapidly when the bees seem to be working mostly on the palmetto, notwithstanding it is seldom that a bee found on its bloom has its sack half or even a third full of honey. Well, the tree is now past the prime of its bloom, which has been profuse, and there is almost no white honey in the hives; there is less brood than ever known before at this season; and although colonies that have been well cared for are mostly in fair shape, some have been lost through neglect, as many of our bee-keepers had to give their time to other work in order to bridge over the first and only season *not giving a paying crop* of honey to the skillful apiarist when prepared to receive it that I have ever known or heard of in this part of Florida.

The mangrove is sprouting out in fine shape from roots and lower trunks of the injured trees, and will probably give quite a crop of honey next year, and a full crop the year after. Don't put us in "Blasted Hopes," as our courage is good yet.

Hawks Park, Fla., July 29, 1886. W. S. Hart.

NOTES FROM ONE OF OUR FRIENDS IN SOUTH AFRICA.

THE POSSIBILITY OF SHIPPING QUEENS FROM THERE HERE.

MR. ROOT:—Your name is too well known in bee-circles to escape the notice of any bee-keeper, even one in South Africa, where bee-keeping has little or no status. I have been a bee-keeper over 25 years, 15 of which have been spent in this colony, in which, until very recently, I have lived almost wholly unenlightened as to the immense advance of bee-keeping during that interval. Of course, therefore, I have been a disciple of the old school, left to his own observations. Some of these are given in the transactions of the Naturalists' Society of this Province, a copy of which I take the liberty of sending you. Since its publication I have happily become acquainted with the *British Bee Journal*, etc., and with your most practical Gleanings, a copy of which is now before me. From these I have been impressed with the fact of the great demand for foreign varieties of bees, with a view of improving bee-strains. This has led me to draw the attention of the bee-world to the supreme excellence of the S. African breed, reference to which has been made more than once in the pages of the *B. B. J.*

From an advertisement in the latest issue of this journal, if you should see it, it will be gathered that Frank Stroud, my son, who has been recently engaged in the rearing of a large number of the best quality of queens, under my own immediate supervision, is prepared to forward such African queen-bees, pure bred, as may be required, guaranteeing their fertility; or nuclei in working condition. The price mentioned is calculated for a single queen only, though where a large number is sent, the cost will be very much less.

S. African bees are a mingled race, probably, of the old Egyptian and brown bee, with a dash of a grayer variety; but they are inimitable workers, and by a long way superior in every respect to the European bee of my earlier experience. The winters here are naturally not quite so severe as in Great Britain, for example; but the droughts here at times are terrible; and how bees live through them, much less increase and multiply, and gather honey nothwithstanding, is indeed a marvel. When, however, bee-forage is about, their energy and activity are equally remarkable, early and late, all the year round. They have no diseases, and are, I should say, an improvement even upon the Ligurians if only in this one particular.

As you are a large importer and grower of foreign bees, and your influence widely felt, I hasten to bring these facts to your notice, believing that an acquaintance with the "Africans" referred to would immensely benefit all who are interested in bee culture and honey growth. I should be glad of any suggestions you might be pleased to offer as to the best means of transporting bees from this quarter to you, the kind of cage you would recommend, etc. J. W. Stroud, M. D.

Port Elizabeth, Algoa Bay, Cape Colony, S. Africa.

Friend S., we are very much pleased indeed to get this report from so far away. I presume your son Frank is working with the aid of movable-frame hives, and all modern implements. We should be very glad to know how much honey you get, in an average season, from a colony of these South-African bees. I think there is hardly any possibility of sending bees by mail this great distance; but perhaps you might send them to Australia, or some other point where Italians are kept, so that they could be compared side by side. Doubtless some of the readers of our journal will be glad to correspond with you in regard to the matter; and if you can not send us any live bees by mail, please send us a few dead ones; or, better still, fill some of the workers with honey, and then put them in a very small vial of alcohol, plugging this up in a wooden block for safety. We will try mailing you a block already prepared, as it may save you some time and trouble.

WEIGHING QUEENS' EGGS.

Can a Queen Lay Eggs Enough in a Single Day to Overbalance Her Own Weight?

PROF. COOK PROVES, BY WEIGHING THE EGGS AND WEIGHING THE QUEEN, THAT SHE MAY.

DEAR MR. EDITOR:—As I wrote you, we are carefully investigating the laying powers of a queen, and we find that the number of eggs that the queen lays per day is no more surprising than the quantity by weight. Mr. Cheshire states that the queen in spring "will turn the scales at three grains—feeding adding fully half a grain more." He says that 90,000 eggs weigh 270 grains; hence 3000, the daily product of a good queen, would weigh nine grains, which would be nearly three times the queen's weight.

You expressed doubt, Mr. Editor, and no wonder. I have found Nature's laboratory so full of wonders that I have learned to doubt, or, at least, deny, no statement like this till investigation shows it to be unfounded. My students and I took a queen, ¾ Syrian and ¼ Carniolan, or about that, and carefully weighed her on scales that weigh to one ten-thousandth of a gram. She was weighed by two separate parties, and on different scales, and weighed .2299 grams. Multiply this by 15.431 and we find her weight 3.548 grains. The queen was carefully lifted from the comb while laying. We see, then, that this queen weighed a little more than one-fifth of a gram, or a little more than 3½ grains.

We next weighed a piece of comb full of eggs, which had been carefully dusted, both by blowing and by use of brush. It was laid on a smooth dusted board, and handled by metallic forceps. I then carefully removed 20 eggs, which were carefully weighed. The weight was .0026 of a gram. Multiply this by 150, and we get the weight of 3000 eggs, the number that a queen will lay in a day at this season. I then removed 40 more eggs, and again weighed the comb. By subtracting this weight of the comb from the original weight, we found the weight of 60 eggs, which agreed almost with the weight as determined by weighing the 20 eggs previously. Thus the weight of 3000 eggs is .39 of a gram, which, reduced to grains, gives six grains. Thus it appears that, in this case, the queen may lay 1.7 times her own weight. Unless the eggs vary in weight—and why should they not?—Cheshire has got the eggs too heavy by ½ their weight.

We shall repeat this experiment with several queens and their eggs. We shall also weigh eggs just laid, and those just ready to hatch, and compare weights.

Now, Mr. Editor, you must remember that your name is Amos, not Thomas, and never doubt again.

A. J. COOK.

Agricultural College, Mich., July 21, 1886.

It would appear, friend Cook, that Frank Cheshire had already made the experiment when I wrote you. Of this I was not aware, for we had not yet received the complete numbers comprising Volume I. of his book, and in this case I shall have to beg his pardon and yours also. Yes, I will try to remember that my name is Amos and not Thomas. It is not often that I feel like demanding so much proof; but I hope I shall be ready to accept truth when it is made so plain as you make it. When you talk about your scales that will weigh queens and queens' eggs, I confess I begin to have a good deal of reverence for the men who can make and use such instruments. Then it is indeed true, that, bound up in the small body of a queen, or mother-bee, are the necessary arrangements and vital forces to take the concentrated food furnished by the workers, and convert it into several thousand of these tiny eggs, each one having a separate life-giving principle bound up within it, each one incased in a perfect pearly shell of its own, and in one short 24 hours she may produce these finished eggs in quantities numbering thousands, and in weight two or three times that of her own body, even when said body is full of eggs. I feel that, if I have been a doubting Thomas, I am now, with the facts you give, ready to say with doubting Thomas, in words expressive of unquestioning faith, "My Lord and my God;" and, "How marvelous are thy works!"

AN A B C SCHOLAR'S EXPERIENCE.

MOTHS, WIDE FRAMES OR CRATES, STINGS, ETC.

MY success with bees, all things considered, has been good. When I began I knew only that bees make honey, and sting, and that there are workers, drones, and a queen. For the first twelve months I had a mortal horror of the moths, nor did I get over it until Root, in GLEANINGS, declared that he would not give 25 cents to have the whole tribe of moths abolished. If the moths have ever harmed my bees, I have seen no evidence of it. Moths do ruin combs that are off the hives, and left carelessly exposed.

WIDE FRAMES OR CRATES.

Last year I used section boxes and separators; but it was such a job to get the wide frames off the hives, that this year I discarded the wide frames and section boxes, substituting for them ordinary frames with fdn. starters, ¾ or 1 inch wide. I am much pleased with the change. However, there has been a good deal of drone comb and brood in the honey-frames. One of your correspondents affirms that a remedy for this is to fill the frames with fdn. Is he right? Can this be depended on? If it can I will fill every honey-frame, next season, with fdn. I would have done it this season to help the bees along had not another of your correspondents affirmed that bees get along with their comb-building just as fast without as with fdn. His experiments seemed to have been conducted carefully and fairly. Please state how this is. Foundation costs enough to make one want to know the real facts about it. In the use of starters I found out the importance of having the starters go very near the uprights of the frames. Where I let them extend only within an inch of the uprights, the bees would build straight to that point and then go crooked, clear over to an adjoining comb. At first I put all my colonies on the ground; that is, on half-bricks laid flat under each corner, but the spiders and ants bothered so much I put legs to all my bottom-boards, and I am much pleased with the change.

KEROSENE FOR ANTS.

Only a few weeks ago one of my colonies was invaded by ants. All I did was to throw down my inclined alighting-board, and pour a little kerosene on the legs of the bottom-board. Had the hive been on or very near the ground, the ants would not have desisted until by some means they were thoroughly exterminated.

SHAKING INSTEAD OF BRUSHING THE BEES OFF.

A word about my experience as to stings: The veil and gloves made me feel so muffled and cramped that I have generally done without them, preferring a few stings to the cramped feelings of working under cover. But about six weeks ago, in taking the honey from a hive I was so unmercifully stung that I had to walk off and get both veil and gloves. Since then I have taken honey from hive after hive without one single sting, and without the use of either veil or gloves. The great difference in the behavior of the bees is not due to atmospheric conditions, scarcity of flowers, or any thing else but my method of doing the job. When I was so badly stung I used a brush to get the bees off the frames of honey. I never brush them off now, but shake them off by a sudden motion of the hands and arms, as recommended by you. Tell your beginners that bees do mind being brushed off the combs, but they do not mind being shaken off. Of course, there should be an inclined pathway to the hive in front, and on this or in front of the hive the shaking should be done, so they can readily crawl in. They behave very much as they do when a swarm or a dipperful from a swarm is poured in front of the hive. This may seem a very small matter to experienced bee-keepers; but the difference between twenty stings and no stings at each hive is a considerable thing. Besides, *every* bee is easily shaken off without any violent use of the muscles. My bees did so poorly at side-storing that I shut up all that part of the lower Simplicity hives devoted to wide frames and section boxes.

What do you and your correspondents think of fdn. with wires molded into it? What is the additional cost, and is it worth one's while to adopt it? JOSEPHO.

Tuscaloosa, Ala., June 28, 1886.

Friend J., there is quite a difference of opinion in regard to wide frames or crates. Dr. C. C. Miller says, on page 35 of his book, "A Year Among the Bees:"

> An objection to the use I made of wide frames was the bits of comb and honey between the bottoms of these frames and the tops of the brood-frames. This might be remedied by using the Heddon skeleton honey-board. Another objection was the great amount of labor entailed. For one not over strong it made a great deal of heavy lifting. Yet I secured some good crops of honey by it, never in more satisfactory shape, and I am not sure whether I can do any better by any other system, if I do not take into account the item of labor.

This might make it a question of circumstances with the bee-keeper. Foundation will surely prevent having your frames filled with drone-comb. As to whether it pays better for comb-honey to let the bees build natural comb in the brood-frames or put it in fdn., remains undecided. Your suggestion in regard to having the foundation go clear up against the uprights of the brood-combs is an excellent one.—Kerosene is probably a good remedy for ants.—More than one of our new pupils have made the same discovery you have when they undertook to brush bees, especially if the brush was a stiff one—like a stiff broom, for instance. The brushes we advertise for the purpose irritate the bees little, if any.—In regard to foundation with wires imbedded, the way it is made by Van Deusen & Sons, it answers a good purpose without question; but I believe most of the friends prefer the plan laid down in our price list and A B C book.

FEATHERING—GETTING QUILLS.

MRS. CULP'S SCHOLAR, AND HOW HE HAS PROGRESSED.

THE first article I ever wrote for a bee-journal appeared in GLEANINGS, June 15, and was entitled, "Just Hatched." In your appended note you say, "Don't fail to tell us more about it." With hearty thanks for your kindness, I comply with your request.

Six weeks ago I knew nothing of apiculture nor of bee-literature, having never read with care a single article on the subject. Since then I have gone through A B C and Cook, reading nearly every thing in both, and re-reading much of their contents; and I have almost devoured several back numbers of GLEANINGS, handed me by a friend. I am greatly pleased with GLEANINGS in every respect. I find in it no bitterness against other journals on apiculture, and very little *hatefulness* between its contributors. It does not attempt to snub the Almighty, nor does it treat religion as something to be shunned, if we would be safe. Altogether, I feel as though I had got into good company.

I have four colonies, all from Mrs. Culp's apiary, two of them quite recently, and they are getting in lots of good work. They have received 72 new frames filled with foundation, the most of which is *done up;* and they have done some work in sections besides. I have formed one nucleus, which affords me great pleasure, and opportunity for observation and study. I hope to grow this nucleus into a strong colony before fall.

I have visited several small apiaries, and two of some note, and I find this a fruitful practice for gaining knowledge. How I should love to visit "The Home of the Honey-Bees"!

I have assisted in almost all kinds of apiarian work. I have beheaded drones, clipped queens, plucked queen-cells, have had queens hatch in my hands, taken queens from hives, introduced queens, hived swarms, transferred colonies, extracted honey, etc.

In the last few weeks I have put together about 300 frames, and all these I have wired; and about one-third of them I perforated with a brad-awl, that they might be wired. I am greatly in favor of wired frames. To prevent sagging I ordered tin strips 3½ by ¼ inch, which I nailed over the top-bar and down on to the end-bars. I have put $25.00 worth of comb foundation into frames for myself and others. Comb foundation is a great invention, and its use should become universal, I think. It pays to put it in well. I first varnish one side of the comb-guide with melted wax. This wax holds the foundation much better than the new wood will; and after the foundation is in I drop melted wax on its upper edge in four or five places, and especially at each upper corner. All this takes time—a little time; but it is the stitch that saves nine.

It does not do well, I find, to hive bees at swarming on frames of comb foundation, as they are so warm then, through excitement, that they melt the wax of which the foundation is made. I still like the chaff hive; but I believe the extra box for the upper chamber would often be an advantage. I think I shall try it and see. A box, made two sides of pine and the other two of heavy tin or sheet iron, would have room in the chamber, and yet allow the frames to run across the lower ones as they do.

She whom my children call "ma" is delighted with the bees. She sends many thanks for your kind remembrance of her. J. S. RICKETTS.

Hilliard, O., July 6, 1886.

Friend R., your suggestion of making an upper story to set inside of the upper story of the chaff hive, of part wood and part tin, is ingenious, but there would be one trouble with it: It would not be conveniently interchangeable with the regular Simplicity hives. —We are glad to note your enthusiasm and zeal, and we hope it may bear good fruit. We have labored hard to see that nothing goes into GLEANINGS reflecting on any other bee-journal; and we mean to try still harder to let nothing uncourteous be seen on its pages toward anybody. Of course, we expect to expose frauds when nothing but exposure will stop them; but we mean to do even this in a kindly spirit.

HOW SOME A B C SCHOLARS SUCCEEDED.

BRINGING STARVED BEES TO LIFE, ETC.

WE had a swarm of bees come to us about the middle of July, 1882. Mr. L. went to one of the neighbors and borrowed a box hive, and the hired man hived them. The hive was glassed on one side, so that, by opening a wooden door, we could look in and see them work, and we watched them very closely.

The basswood yield was very good that year, and they made honey enough to winter on. We put them in the cellar in the fall, and every warm spell through the winter we would go and listen to see if they were living; and sometimes, if we did not hear them, we would jar the hive, we were so anxious to know whether they were still alive. But they survived all such hardships.

Mr. L. sent for an A B C book in the spring. About the tenth of April he put the bees out of doors; and during apple-tree bloom he had them transferred to a Langstroth hive. The tenth of June they sent out a swarm, and it clustered on the body of a tree; and if we were a little nervous over the first swarm, you will pardon us; but with milk-pan in one hand and wing in the other, Mr. L. soon had them in the hive. The next swarm was not so easily managed, as they came out the second time, and we did not know what to make of that, so we went to the A B C book and found that was a freak of the young queen. After coming out two or three times they settled down in their new home.

The third swarm we sent back. The first swarm made 44 lbs. of nice section honey. Mr. P., who keeps 90 swarms, said it was the nicest honey he ever saw. Mr. L. bought two colonies in the fall for $5.00 each. The next spring he lost his original swarm. He had no smoker, so he could not look at them. He thought he would wait and see whether his bees lived through or not before he bought one. We watched them to see if they came out on all warm days. One day we noticed that that colony did not come out when the others did, and there was another colony we could not see any flying from, so I went out there and I saw two or three bees at the entrance that could just crawl. When Mr. L. came to the house I told him they were starving to death, and he opened the hive and found a good many of them on the bottom of the hive, and those on the frames could only flutter their wings a little. He said he did not think we could do any thing for them; but he brought them in and put some strained honey in the comb, and in two hours they were flying. The other colony were all dead. Mr. L. got a smoker in the spring. That year we had no new swarms, but had 397 lbs. of honey. One of the colonies bought made 123 lbs. Last year the four colonies averaged 83 lbs. apiece, and increased to nine; this year to 20. We take GLEANINGS, and like it very much.

Harford, Pa., July 7, 1886. MRS. H. M. LINDSY.

LEAF-HOPPERS.

Do They Really Secrete Honey?

PROF. COOK GIVES US SOME INTERESTING FACTS IN REGARD TO THIS FAMILY.

FRIEND ROOT:—We send you, by to-day's mail, some insects which we find in great quantity, producing a sweet substance we suppose to be honey-dew. They seem to hatch on hemp, and osage orange. When first seen they are white and linty until they get their wings. Bees are working all hours in the day on this substance. Can you tell the name of the insect, or are they a common thing? I never saw such before this year. Z. G. COOLEY.

Norwalk, Iowa, July 13, 1886.

Prof. Cook replies in regard to the above as follows:—

These are not plant, or scale lice, but are leaf-hoppers, which are readily known by their broad heads, prominent eyes, and sharp-crested thorax. The larvæ of many species secrete a liquid in which they live and feed. This liquid contains air-bubbles, and looks not unlike freshly ejected spittle from a clean mouth. These leaf-hoppers are so called, because they live or feed on leaves, and when disturbed they hop away. One, the grape-leaf hopper, is often a serious pest to the vine which gives it its name. Though these are not plant, or bark lice, they do belong to the same order—*Hemiptera*, or bugs, as can be seen by the prominent beak or strong sucking-tube, which is bent under the body when not in use. You, Mr. Editor and others, have noticed the frothy liquid surrounding these larval leaf-hoppers on an evergreen-leaf or grass-blade. I have never discovered that these secrete a nectar, nor heard of it before. I am led to wonder if the same plants did not harbor and provision a colony of plant lice which supplied the sweet. The matter should be sharply looked into. If these leaf-hoppers do secrete nectar, it is a new and interesting point. A. J. COOK,

Agricultural College, Mich., July 20, 1886.

ANOTHER WAY FOR KEEPING THE QUEEN OUT OF THE SURPLUS.

ONE METHOD OF PREVENTING AFTER-SWARMS.

WE have always had some difficulty from our queens going into the surplus-apartment and occupying a part of the combs. If we are working for section honey it is not only provoking, but ruinous to the honey-crop, to have the queen lay eggs in the sections, where we want nice white-clover honey; and it is equally provoking, if less ruinous, when working for extracted honey, to find combs that should be solid with honey, half filled with brood. Out of many methods tried, the following is the only perfectly successful one with us:

We take a piece of perforated zinc, just long enough to fit in the hive lengthwise and 18 inches wide. We bend this zinc in the shape of an L, thus ┐, the long arm of the L just reaching from the top of the brood-frames to the bottom of the hive. This is now put between the 4th and 5th frame, leaving four frames on one side and six on the other, when the short arm of the L will just cover the six frames (of course before putting on the zinc we see that the queen is on one of the six inclosed frames). Now, if the zinc has been carefully fitted, the queen is securely caged upon these six frames. If the queen is inclined to come out at the entrance, and go around, a strip of perforated zinc may be tacked at the entrance, in front of the six inclosed frames. We have not found the latter necessary, only where we wished to prevent swarming; if natural swarming is desired, the zinc in front of the inclosed frames must be removed or the queen could not leave the hive.

The benefits obtained by thus caging the queen upon six frames are, 1. We are not troubled with brood where we want surplus honey; 2. We are not troubled with honey where we want brood; the bees empty almost every cell from the inclosed frames, and they are filled with brood from top to bottom; 3. The four frames upon the other side of the zinc division are filled solid with honey, and make grand combs for winter; 4. The swarming business is absolutely under our control.

When a swarm issues we lift off the surplus, set aside the brood-chamber (lower story), put another in its place filled with empty combs, if we have them; if not, with wired frames having a strip of foundation 1½ inches wide attached to the top-bar. We usually take out one frame from the old brood-chamber and put in the new. The surplus is put on this new brood-chamber upon the old stand, and the swarm hived in just the same location it came from, while the old brood chamber is removed to a new location.

The benefits derived from this method are, so far as my observation goes, 1. The new swarm goes to work in the surplus at once, with all the energy and stimulus which swarming gives; 2. They are in the humor for comb-building; and if we want nice straight worker-comb built, we can get it done rapidly in this way; 3. A large number of the old bees from the old brood-chamber (now on a new stand) will return to the new swarm. The colony in the old brood-chamber on the new stand will be so weakened that, when the young queens hatch, there will be no swarming fever, and we have no after-swarms. G. C. JOHNSON.

Fountain City, Ind., July 7, 1886.

TENNESSEE AS A HONEY STATE.

THE SCENERY FROM LOOKOUT MOUNTAIN.

OUR winters are so mild that we can winter with perfect safety on the summer stands. This I consider a great advantage over the Northern States; and could bees be wintered there with as much assurance that they would come through all right as there is here, I do not think that the wintering problem would be discussed as much as it is; still I believe it requires one-third more stores for a colony to winter on in this country than it does in our extreme Northern States. The reason of this is, that they rear more brood here before there is any honey to be gathered than they do in the North. It is not uncommon for bees to have four full frames of brood by the first of March, and for them to throw off swarms the fore part of April.

We do not have any spring dwindling here. Our colonies seem to be always strong, and ready for work when there is any thing for them to do.

The first honey that comes in in the spring is from the peach bloom. This is generally from the 15th to the 25th of March. After this comes other fruit bloom, and some other wild flowers and forest blooms. This keeps the bees in fine shape until the first of May; then comes the poplar bloom, and at this time the bees are in the surplus-boxes doing fine work, as there are large quantities of poplar here. About May 10th the white clover commences to bloom, and continues to bloom for six weeks. We have not as much white clover here as you have in the North, but in certain localities there is an abundance of it here. Before this is out of bloom, the basswood, chestnut, and persimmon bloom; and while they are still yielding honey, the famous sourwood puts forth its bloom. This produces well, and the sourwood honey is very fine, except that it is rather thin when first gathered. The sourwood bloom lasts until about July 10th, and from then until July 21st there is not much for bees to work on. Now comes in the sumac, and the bees are doing finely on it, considering the cool nights we are having. During the whole month of August we have plenty of pea bloom (the cow, or clay pea). There are large fields of peas sown in this section of country. We have considerable goldenrod and fall aster. There are a great many honey-plants that I have not spoken of, and some of them are of no little importance. Among them are the different kinds of mints; also spider plant and black locust. We have our bees located in a little valley, the Sequatchie. This is between two mountains — the Cumberland and Walden Ridge. Our bees have access to the valley, and the sides and the top of the mountains for some distance back.

As Ernest asked, in last GLEANINGS, in regard to the honey-flow being prolonged where bees had access to both the valley and the mountain, I will say it is greatly an advantage with some bloom, such as chestnut, sourwood, and poplar; and if there is no bad weather to stop the bees off they will follow it, even for several miles on the top of the mountain; but I believe he was referring more particularly to white clover. I would say that there is but little if any white clover on the mountains in this country. Friend Lawson is located right at the point of Lookout Mountain, and right where the "Battle above the Clouds" was fought. The breastworks that were thrown up at that time can be seen in his yard, and it is here that one can command a full view of the city of Chattanooga, or take a telescope and look into seven States; and here with the naked eye you can see the Tennessee River as it winds around the city of Chattanooga to the foot of the mountain, then back, making what is called the "Moccasin Bend."

The climate here is good. The summers are warm, but we do not have the extremely hot weather that you have in the North. It is not often that the mercury is above 90° or below zero.

Some may think this is rather flattering for the State of Tennessee; but let me say, that this land is not always blooming in honey; for this summer has been a poor one for those keeping bees as well as for the farmers; for it commenced to rain on the 14th day of May, and there were only seven days from that time until the 11th of July but that it rained. But so much rain is not a common thing here, as it is generally dry through June and July.

Pikeville, Tenn., July 24, 1886. E. C. KEPNER.

NOTES FROM THE BANNER APIARY.

No. 80.

NON-USE OF FOUNDATION.

YOU say, friend Root, that you do not quite "catch on" in regard to there being no difference whether comb or extracted is raised, when allowing swarms to build their own combs in the brood-nest; but you begin to suspect that bees will store more honey when allowed to indulge in their passion for comb-building.

The point is this: *If* more honey will be secured by allowing the bees to build combs in the brood-chamber, it makes no difference in what *form* the honey is taken in the super. I do not think the first sentence of my little item on page 563 is very clear. I meant to say that I had worked new swarms for extracted honey, and that I considered the advantage gained by allowing them to build their brood-combs was as great as in working for comb honey; that really I could see no difference.

I do think that bees work with greater zest when building comb. This zest could be secured by allowing the bees to build combs in the supers instead of the brood-nest; in fact, this has been suggested by some of my correspondents. This course would defeat the main object of withholding combs or fdn. from the brood-nest; viz., that of getting the honey in the supers, and the brood-chamber full of brood. I know Mr. Jones says he is convinced that combs are an advantage in the raising of extracted honey. I agree with Mr. Jones, and I *think* he will agree with me in thinking that the combs should be in a *super*, with a queen-excluder between them and the brood-nest, and the latter free from combs or fdn., except enough for starters.

Some of those who have been trying this plan of allowing new swarms to build their own combs in the brood-chamber have been troubled by getting too much drone-comb. I think the trouble can be traced to one of three things; viz., too large brood-chamber, too old a queen, or in not putting on the supers *at the time of hiving*. Have the brood-chamber of a capacity not larger than five or six L. frames; put starters of fdn. about ½ inch wide in the frames (they can be put in with a Parker fdn. fastener), put on a queen-excluding honey-board, then a super, either for comb or extracted honey, and have the frames or sections in the super filled with fdn.; or, better still, combs. I take the case of sections from the old hive at the time of swarming, and put it on the new hive, and in 20 minutes the bees are back at work again—working with new energy too—in the very sections that they so eagerly deserted a few minutes before.

W. Z. HUTCHINSON.

Rogersville, Genesee Co., Mich., July 26, 1886.

INVERTING VERSUS ALTERNATING OF HIVES.

THE EFFECT OF INVERTING QUEEN-CELLS AT DIFFERENT AGES.

ARE we not getting somewhat over-enthusiastic on inverting, and prematurely claiming for it what, in exceptional cases, appeared very favorable; but, upon applying it practically, would give a greater number of failures? And are we not losing sight of other arrangements that give us the same results with less labor? For instance, it is claimed by some that inverting a hive or its combs would destroy the queen-cells, and consequently prevent swarming. As I have experimented considerably on that subject, I will give the result of my observation.

About 15 years ago a friend purchased nearly all the bees in this county, something over 100 colonies. These I transferred for him into movable-comb hives. Some of these colonies had queen-cells in various stages of development; but as the colonies were to be supplied ere long with Italian queens, no special attention was paid to their position in the new hive; and as most of the combs fitted best into the frames in an inverted position many were so placed in the hive. Upon examination, shortly after, it was discovered that some of the queen-larvæ were dead, and nearly dried up in the cells, whilst some matured, point of cell upward, as though its position had never been changed. This gave me cause for investigation; and since that time I have conducted numerous experiments; and since the subject of inversion has been agitated, these experiments have been quite extensive, and I have arrived at the following conclusion:

During the entire sixteen days required to mature a queen from the time the egg is laid, there is but a single day when the queen-larvæ of some of the cells may be destroyed by inverting them. The egg remains unchanged until the fourth day, when the egg hatches and the larvæ feed for five days. During this time it is curled up in the cell, somewhat like a ring, and no inverting will destroy it during that time. But now comes the critical time. The bees begin to cap the cell, the larva straightens up lengthwise of the cell and spins her cocoon, occupying one day. If the queen-cell was built in a horizontal position as they frequently are, no inversion will destroy the embryo queen; but if, on the contrary, the queen-cell is in a vertical position, and is inverted during the day that she assumes a straightened-out shape, and spinning her cocoon, and is left in this inverted position for 12 hours, the embryo queen dies; but after a queen has spun her cocoon the cell may be placed in any position without injury—a fact made known to the fraternity when friend Root taught us the use of the lamp-nursery. If a queen-cell is inverted before this time, the queen seems to remain in the base of the vertical cell, she herself retaining a horizontal position, and hatches as a stunted, dwarfed specimen.

Now, what effect, practically, has the occasional destruction of an embryo queen as a preventive of swarming? The natural swarm issues on the very day, weather permitting, that inverting of a *vertical* cell would destroy its inmate; and should this inverting perchance be done at the right hour, the swarming fever has so far taken possession of the bees that usually the swarm issues, notwithstanding the injured embryo queen; and, further, there are usually several queen-cells of varying ages; and if inverting is practiced before the time indicated, a dwarfed queen for the future mother of the colony is the result—an injury rather than a benefit; and this injury may result to us, if we invert for any other purpose, without knowing the condition of each comb inverted.

The advice of Ernest, on page 551, is indeed timely. Some combs may be all kinked and doubled up by inverting, and I quite agree with him on the unsightly appearance of combs whose lower edges are imperfectly built out, occupying space that should be solid with brood; and to fill this seems about the main (and I might say the *only* practical) cause for inverting. Yet this and many other profitable manipulations can be accomplished without inverting, and that is, *alternating*. A hive constructed so that its brood-chamber may be horizontally divided —that is, one half placed on top of the lower half, and arranged to interchange, furnishes all the desired advantages. If the lower edges of the combs are not built solid to the bottom-bar, simply place the lower half on top of the upper half (alternate). The lower edges are now near the middle, and are soon built solid, and filled with brood, not honey, as is usually the case when inverted.

I would not advise discarding our present hives *at once*, by any means; but this is a progressive age, and we will sooner or later adopt more or less of the alternating principle, as hundreds have already done in their surplus-honey arrangements. It reduces the time required to manipulate such a hive about one-half. We simply have to alternate occasionally to equalize the brood; make artificial swarms by removing one case with bees, brood and all. When honey-cases are added we alternate, bringing the center of the brood-nest directly under the sections; and any honey that may be in the brood-chamber is thus brought down below the main portion of the brood from where the bees remove it; and as the top of the brood-chamber is filled with brood it is deposited in the sections.

Right here is an important point over inverting: If a comb is inverted, its *empty* edge is uppermost, and the honey removed from below is stored to some extent in this empty comb, instead of in the sections; and the empty combs, thus inverted, with the additional space between brood-comb and section case, furnishes no special inducement to enter the surplus-chamber; whilst by the alternating plan, the solid brood is brought up close to the sections.

Seventeen years ago I constructed and used quite a number of these hives. The ends of the frames were close fitting to each other, standing on metal strips, all held in place by a wedge; but in later years I have used them with closed, as well as with separated suspended frames, and am so using them to-day; and after carefully conducted experiments with both styles of frames, I greatly prefer the suspended frames, on account of the lateral adjustment; and although both styles can be inverted with their cases, and I have so used them by way of experiment, I can not find any additional merits from inverting, as alternating accomplishes all that is practically valuable in inverting.

Coburg, Iowa. E. KRETCHMER.

DR. BEAL'S WILD GARDEN AT THE MICH. AGRICULTURAL COLLEGE.

ALSO SOMETHING ABOUT THE HONEY-PLANTS BEING TESTED THERE.

AMONG the many excellent things accomplished by Dr. Beal at this College is the "Wild Garden," so called, not because things are allowed to run wild in it, but because the natural herbs and shrubs are there arranged in wards so as to show the natural orders. This is in a ravine; and in the dark shades along the rocky bank are seen the graceful ferns, while in the ponds are the various aquatic plants, many of which, as the pond-lilies and the American and Egyptian lotuses, are most beautiful. Now, friend Root, how I should like to have you with me as I take my daily stroll through this, one of the most lovely places at this College! Oh! but wouldn't you enjoy it? Of late I have been especially interested in some of the honey-plants. Two of the mints are crowded with bees from dawn till nightfall, and by their superior excellence may well make catnip and motherwort hide their respective heads. I doubt if even the horsemint of Texas would more than rival these plants. They both belong to the same genus as does catnip. One is *Nepeta mussini*, and the other *Nepeta nuda*. Another plant, *Eryngium planum*, is a marvel. For weeks it has been thronged with bees. It looks some like the Chapman plant, of which I have written you; that is, the flowers are in balls; but, unlike the Chapman plant, are not very showy. To look at this plant casually we would think it a composite or relative of the teasel, though in fact it is related to neither one, but belongs to the parsley family, which fact would never be suspected without close study. I shall gather seeds, and expect to rival, though not in beauty, the Chapman plant. The two will look well upon one bed together. *Eryngium yuccæfolium*, butter-snake root, an American plant of the same genus, is also an excellent honey-plant, or is so reputed.

A little way from this is the teasel. This looks much like the Chapman plant, though it is of a different family. The bees are wild about it. Did you ever notice the connate-opposite leaves, which form a cup about the stem, and hold sometimes half a pint of water? We have had no rain here for weeks, and yet these cups from Nature's own hand are full of water, and the water is full of decaying insects which have been entrapped, and are now fertilizing the plants. Gray says these cups are often full of rain water; but it can not be rain water. The water must have come from the plant, or they would have dried up long ago.

Another plant, the white verbena, is a great favorite with the bees. This is *Verbena verticifolia*, and is much better, I think, than the common place *Vervain verbena hastata*. The various sunflowers are also fairly alive with the bees. The bees work on these, both for pollen and honey. I have often seen bees loaded with pollen, sipping the nectar. Poor fellows! how tired they must get to thus go doubly loaded! I have seen the poor bees drop to the earth, and rest for quite a time, then rise and slowly make for their hives. I have often seen them also gather pollen from two species of these sunflowers during the same trip. Is not the old notion, that bees visit only one species of flowers during a single trip to the fields, due rather to the fact that flowers "of a feather flock together," than to any special option of the bees?

I should like to discuss many others of these interesting plants, but will wait. In the meantime I give you, my good friend, a most hearty invitation to come and see that the half is not yet told.

A. J. COOK.

Agricultural College, Mich., July 23, 1886.

Many thanks, friend Cook, for your kind invitation, and I may accept it pretty soon. We missed you sadly at our recent meeting at friend Chapman's, which I have mentioned elsewhere. Now please have your pupils tie a little paper bag over those heads of teasel and balls of bloom on other plants, keeping the bees away for 24 or 48 hours, and then see what you find. Where bees are allowed to work on the flowers from morning till night, we have no opportunity of getting any knowledge at all of the quantity of honey the flowers secrete. What you say about the teasel is new to me. I confess I did not know that it secretes water in the way you mention, although we have plenty of wild teasels growing round all about us. I am of the opinion, that bees rather prefer to work on one kind of blossoms, for I have often noticed them in the clover-field where red and white clover were about equally divided. Some of the bees visited the red-clover heads exclusively, and others just as exclusively the white-clover heads, and I never saw a bee go from white to red clover, or *vice versa*, that I know of.

HONEY AS FOOD AND DRINK.

HONEY GINGER-SNAPS.

THE following recipe my wife has used for years with good results: One cup of brown sugar, one cup of extracted honey, a tablespoonful of ground ginger, a cup of melted butter or meat fryings, a teaspoonful of saleratus dissolved in a little hot water, and as much wheat flour as can possibly be stirred in (but not kneaded). Pinch off pieces about the size of a large marble, and roll between the hands. Leave spaces between them in the pan to allow for spreading. Bake in a moderate oven till of a nice brown, and leave in the pan till they are "snappy." In cold weather the materials should be warmed before stirring in the flour. They are perhaps a little tougher than if made of molasses, but good "all the same." They will "keep," if you keep them off the table and out of reach of the children.

A CHEAP HARVEST DRINK FOR BEE-KEEPERS.

When I was a boy my mother used to make a drink for us to carry into the hay and harvest field that we called "ginger beer." It was made of water with sufficient molasses, vinegar, and ginger to make it taste agreeable. Since I have been keeping bees I furnish my men with a similar drink for hot weather.

RECIPE.

One teacupful of extracted honey, one teacupful of vinegar (made also from honey), a teaspoonful of ground ginger and half a gallon of water. It can be used immediately, or will be good all day. I have never had a man or boy who did not prefer this to water. The condiments can be varied to suit the taste. The ginger is a good tonic, and the stomach is not so likely to get "sick" as when water alone is drank. They are not so liable to overload the stomach. When taken into the field for half a day, water gets warm and sickish—not so this drink. It is good all day. EUGENE SECOR.

Forest City, Iowa, July 20, 1886.

CARBOLIC ACID FOR QUIETING BEES, HYBRIDS, ETC.

DOES THROWING DIRT BRING DOWN SWARMS?

YOU ask if my bees are hybrids. I think they are. I send off and get new queens every year or two; but the first thing I know they are all hybrids again. They seem prone to run to hybrids as sparks to fly upward.

If carbolic acid used in smokers makes other bees as cross as a rag wet with it did mine, I do not envy anybody all the fun they will have using it. I used it on one of my best Italians, and they stung me so that I could not shut my fingers enough to feed myself for a day or two. I don't want any more carbolic acid in mine.

Ernest asks one of the juveniles if he really believes that throwing dirt among a swarm causes it to alight. Of course, it does. Our work-hands used to bring them down every time if they were crossing a field where there was plenty of loose dirt. That was before I began clipping the queen's wings, when swarms ran away every day in swarming time. Neither tin pans nor drums, dinner-bells, nor yelling helps a mite; but *hitting* them with dirt or water does.

WHAT MADE THAT TOE-NAIL COME OFF?

Now for that toe-nail of yours. I have been trying to attend to it for some time, but have been just too busy for any thing. Friend Root, you *did stub that toe* — Mrs. Root was right, as she always is. Of course, I know you are honest in thinking that it came off for a little extra filing, but it did not. You stubbed that toe on Huber's cradle as you jumped out of bed some morning in a great hurry, or else you kicked it against the foot-board, or the Jersey cow stepped on it, or the wheel of the market-wagon passed over it while you were loading in lettuce, or your horse trod on it, or you let one of those fifty-cent hammers (the best in the market) fall on it, or else, or else, or else. Why, there are fifty ways that a man with his head in the clouds might stub his toe and never know it, and you are just as sure to have hit upon one of those ways as that your name is A. I. Root.

Vermont, Ill. MAHALA B. CHADDOCK.

Now, Mrs. Chaddock, I do not like to contradict, but I tell you that none of the things you mention have ever happened to that toe of mine. My mother says I was remarkably cautious, even when I was a baby, and I have not got over it even yet. I do not like to be hurt, and so I keep my toes out of the way. It was just as I told you—invisible forces met together as the trustees of a township do when they want to decide about building a bridge. They looked that toe-nail over critically, examining the place where I had gouged into it with the file, and finally decided it should be replaced by a new one—not a new bridge, but a new toe-nail, and it was just as I told you. During all the consultation, including the decision, I was not consulted at all, and yet it is *my* toe-nail. I am well satisfied, for the new one does not bother a bit, but behaves itself just exactly as a well-bred toe-nail ought to do.

NUCLEUS COLONIES.

HOW TO BUILD THEM UP FOR WINTER.

IT is probable that some who buy nucleus colonies do not know how to build them up to the best advantage; and a little help for them would not be out of place. Where fall pasturage is plentiful it would be a very easy matter; but where there is none, feeding must be resorted to in order to get them in good shape for winter. When such colonies are received from the express office the first thing to do is to get them out of the shipping-box and into your hive.

The best way to do this is to sprinkle from one-half to a pint of thin sugar syrup through the wire cloth, on the bees; and while they are filling themselves with it, carefully remove the wire cloth and the sticks that hold the frames in place. Have your hive placed where it is to stand permanently, and then carefully lift each frame and set it in your hive, placing them to one side of the hive, with a division-board next to them to keep them warm, and from running all over the hive. The bees are now in your hive, and to make them boom is next in order.

It would be best and cheapest to have on hand at least three frames filled with foundation, though empty frames will do; but it will take more time and more sugar. The next thing in order is the feed; and probably the best thing would be a syrup made after the plan given by friend Doolittle on page 762, Nov. 15, 1884. This syrup does not candy in the combs; at least, not as much as honey. I give the plan for making it, in his own words, so it surely will be right:

"Fifteen pounds of water was put into a large tin dish, and brought to a boil; then 30 lbs. of sugar was poured in and stirred for a moment till partially dissolved, when it was left over the fire till it boiled. Upon taking from the fire, 5 lbs. of honey was poured in, and the whole stirred enough to mix thoroughly."

Commence by feeding about one pint of this syrup every night, using any kind of feeder that you may prefer. After feeding four or five nights, spread the combs in the hive and place one of your empty frames, or one filled with foundation; and when this frame is well along toward completion, put in the second and then the third, putting in frames only as fast as the combs are built, or the foundation drawn out. If you had a three-frame colony to begin with, probably these three extra frames would be enough; but four or five would be better. If you use foundation, the combs, of course, will be straight; but if you do not, you must watch and see that the bees are building them so; and if they are not you must help them.

When they have three or four frames well filled with brood you can begin to feed heavier, so that they will have at least 20 lbs. of the syrup stored and sealed by the first of October for winter use. If they are in a chaff hive, with good chaff cushions over them, they are ready for winter; and if they are not, you must fix them up in some way so they will keep warm and dry.

Some may ask whether it would not be cheaper and less trouble to wait until spring, and buy bees then. It might be that it would, but I think that the experience a beginner would gain by building up nucleus colonies in the fall would well repay them for their time and trouble; and if they are careful they would have good strong colonies to begin with in the spring.

Remember, you must feed only at night, and be up early in the morning and remove the feeders, for your neighbors may have bees that would like the fun of robbing your bees. **F. W. MOATS.**

The Bend, Defiance Co., O., July, 1886.

WHAT SHALL BE DONE WITH UNFINISHED SECTIONS?

CONTRACTING, REVERSING, ETC.

GLEANINGS is at hand; thanks to Jas. Heddon for his two last articles. Now will he tell us what he does with unfinished sections? I always used wood separators till using his 7-to-foot sections and no separators. This year, for the first time I have got along without separators in some cases and get fair sections; but in putting back those part full they will be bulged badly. If a part of a section is capped half way, the rest will be built beyond the part capped.

CONTRACTING, AND RESULTS.

All hail to bee-men like Doolittle who care enough for those new in the business to give their experience. Will a contracted brood-chamber work in all localities? I contracted to six and eight frames—9½×14½, when I put on sections, and, in 60 colonies, I had 500 sections that were spoiled with pollen. The sections I used were 1⅞ and 1¾, with and without separators, and I saw no difference in the amount of pollen.

Heddon's reversible frame is the best, I think. Will not reversing frames cause bees to store pollen in sections? What do you think of a bee-keeper who sells his honey just as he takes it from the hive, in wide frames, and lets the grocer tear out the sections and bruise more than half? He takes GLEANINGS too. I sold scraped sections at 13 cts. in the same town in which he sold his at 10 cts.

I look for the open-side sections to replace all others.

The season opened nicely. Swarming began early, and kept up all through clover bloom. I lost a good many queens by swarms going into other hives. I clip all queens. I have no trees for them to alight on. I tried

HEDDON'S PLAN

of swarming, and did find chilled larvæ in the old colony. It leaves the old one very light before moving to a new stand, in some cases.

Hopkins, Mo., July 21, 1886.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from July 15.

CHAPTER XXI.

The earth is the Lord's, and the fulness thereof.—PSALM 24: 1.

Many kind comments have come in regard to the former chapters of this my book on gardening; and one or two have complained that I have not given sufficiently the dark side of the matter. Well, although I have touched upon it all along, perhaps I have not given it enough in detail; and the past few weeks have given me an opportunity of writing a good chapter on the dark side. Up to July 1st we had hardly enough of *any thing* in the way of garden-stuff. But after that, first lettuce began to be somewhat of a drug on the market. We wrote to the city markets, but we were told that it could not be used at all. Then green peas began to be produced in larger quantities than we could make use of. A trial shipment of ten bushels was sent to Cleveland. They brought 70 cts. a bushel, and it cost 25 cts. a bushel to pick them and put them on the cars. After paying freight, but little was left. For a time we thought beets were always a great staple, and there seemed to be no such thing as getting enough. Now we have, however, perhaps 50 bushels, and no one wants them; that is, we have not yet found a market for them. None seem to be spoiling, however, and we are inclined to think the people will want them again after a little while.

The most discouraging article, however, has been early cabbages. As no such thing has ever been raised in Medina County, I, contrary to the advice of some of my helpers, planted largely. I expected to compete with the Southern trade. Well, my cabbages have done finely. I think that fully 90 per cent of the plants have made beautiful hard heads. We started them first on the wagon at 3 cts. per lb.; $2.50 per 100 lbs., or $40.00 per ton; and, by the way, I wish to say right here that it seems to me the only just and fair way of selling such stuff is to sell it by weight. We now sell cucumbers by weight, tomatoes by weight, cabbages by weight, and I begin to think the proper way would be to sell celery, bunch onions, and bunch beets, at so much a pound.

Well, when the cabbages didn't bring 3 cts. per lb. readily, we reduced the price to 2 cts. per lb.; $1.75 cts. per 100 lbs., or $30.00 per ton. This gave them another start; but for all that, I found we were not selling one-fourth as many as were getting mature. Some heads bursted open, or snapped with a report, while we held them in our hands. Others began to show symptoms of decay. Two of our best salesmen started for a large town 20 miles distant, with a two-horse load of cabbages. They did not sell enough to pay for their own time and the team. Finally we sent some to Cleveland on commission. They reported that the city was full of cabbages, and that they could hardly dispose of them at any price; and finally they were sold for just enough to pay freight and commission. At the same time that cabbages were getting to be so plentiful in our town they could hardly be given away, potatoes dropped rapidly from a dollar to 75 cts.; then 60 cts.; then 50 cts.; and a day or two ago I bought a load of them for 35 cts. per bushel. We can never raise potatoes on our grounds for 35 cts. per bushel; that is, it does not seem to me that we can. Apples have hardly brought 50 cts. a bushel at any time in our market; and yesterday I bought a load of nice picked apples for only 10 cts. a bushel, the owner saying he would rather sell them at that price than carry them home again. The total receipts of our market-wagon, many days, would not pay for the help on the wagon and on our ten acres, to say nothing about the cost of tools and manure. To add to the difficulty, others are bringing in produce without finding sale. A man wanted to sell us some "Jersey Wakefield" cabbages. I asked him how he came to have them so early. He said that he raised them from plants he bought of us, *of course*. When urged to have us take them off his hands at some price, I asked him if he had been to the neighboring towns, and he said he had supplied them with cabbages in every village and town within ten or fifteen miles of where he lived. What is to be done? I thought of reducing the wages of my helpers; but as I considered them one by one, I felt as though I hadn't the heart to ask them to work for less wages than they were already receiving. Our poor and inefficient help has all been weeded out. We have none but good men and good boys; that is, in their respective lines. The trouble is, that peace and plenty reign throughout our land, and everybody has an abundance of every thing without buying very much. Is it a trouble? Why, I think not. A drought or a flood, or something of that sort, might have enabled me to get better prices for many of my products; but surely no sane man would wish for such calamities to come on himself and his neighbors. Well, what did A. I. Root do in such a state of affairs? I studied the matter over carefully, and told my hands just how we were situated. To some of them who, I felt, sympathized with me, and with whom I felt it would be wise to state it so, I spoke something as follows: "Friends, we shall have to make it a subject of prayer. Let us ask God to give us wisdom, and tell us what to do in this crisis." Before asking God's help we want to be sure that the business we are engaged in is one that is pleasing in his sight. In my own case I prayed that God might help us to dispose of our produce, not solely because of the money we wish to make, but because I felt my undertaking in writing this book was a right and proper one, and that the few dollars that I might make in market gardening were a very, very small item when compared with the matter of setting our American people at work at their own homes in tilling the soil. Now, I have had so many answers to prayer, especially where I have prayed over business matters, that I presume I ought to have had faith that God would help us in this emergency as well as in all the others scattered along through the years I have been trusting *him* and going to *him* for aid and guidance. The only doubt that troubled me was as to whether my undertaking was really right or not. There are some features of the business that seem a little questionable. For instance, I had cut off the trade of the grocers of our town not a little. Then, again, I had, to a certain extent, harmed the very class I wished to help; that is, the farmers round about us who have been in the habit of selling produce in our town. We have been raising so much of certain vegetables that it left them no chance to sell any at all. I prayed over this, and prayed for them as well as for ourselves and our plans.

At the convention in Detroit, quite an animated discussion came up at one time because our bee-journals showed too much of the bright side of every thing; and a good honest friend of mine from Canada declared that, whenever I touched on the subject of "blasted hopes," I always wound it up with something bright and cheerful; that is, my black clouds all had a silver lining. I have thought of this a good many times, and I do not know but that I shall have to plead guilty, at least in this way: I do believe that God intended from the beginning that all of our black clouds should have a silver lining, and that, through great trial and tribulation, should come great victories and happiness.

When I fall I shall arise; when I sit in darkness, the Lord shall be a light unto me.—MICAH 7:8.

Now, I do not mean to say that things changed *right off* as soon as we commenced praying. For a time it seemed as if they went on just as before, or even worse. This was no new experience with me. I knew already, or at least I certainly ought to know, that, if our undertaking were a right and proper one, and that, if our prayers were in a line with the text, "Thou shalt love thy neighbor as thyself," an answer would certainly come. One of the obvious ways to dispose of produce is to advertise; but I could not advertise cabbages to the friends who read GLEANINGS. The expense of transportation would be, to at least most of you, more than they are worth. The only avenue open was our county papers, and so in went an advertisement something like this:

JERSEY-WAKEFIELD CABBAGES.

We have a fine lot of these excellent cabbages now ready for delivery. The price will be 2 cts. per lb.; $1.75 per 100 lbs., or $30.00 per ton.

We then went to the grocers of our town, and told them that we would furnish them fresh cabbages, cut to their order in any quantity they wished, at the ton rate. At first they did not seem inclined to handle our cabbages at all. They could get them from Cleveland, even cheaper than we could raise them; but when the country folks began to call for "Root's crisp hard cabbages," they began to give us some orders. At the same time, farmers stopped their buggies as they were going past, and asked for a cabbage or two. They soon discovered that it was indeed a fact, that our cabbages, fresh from the field, were a good deal nicer than any thing that had been shipped in from the large cities, and a good healthy trade started. I was so anxious to have the crop saved, that I gathered a great number of them myself, going over the field, and selecting first every one that looked as if it would burst very soon. Where they had actually snapped open, we offered them at a discount; where badly broken, at half the advertised prices. Now, these broken ones are as good as any for immediate use. In fact, they are usually the finest and most crisp cabbages in the field; and many people who wish to economize soon took advantage of this, and we began to see daylight in the cabbage-trade. At the present writing, very few have been lost. Where they are badly bursted, and have become discolored by the sun and air, we give them to the poultry.

Within five or six miles of us is a beautiful lake which has lately become quite a pleasure-resort. Our advertisement called the attention of the hotel-keepers at the lake to our business; and when men came to our gardens and began to make offers for the stuff just as it stood in the field, I began to feel indeed that God had heard our prayer.

"How much will you take for that lot of celery, just as it stands right there in the dirt?" said a customer a few days ago.

I told him that, as it was all we had that was really fit to put on the wagon, I could not take less than 5 cents a stalk. He did not take it at that figure, but thought he could give 4 cents. Now, none but those who have been through similar trials, and it seems to me that none but those who have been praying over such matters, can realize with what feelings I thanked God inwardly for this one answer to our prayers. Instead of having to draw our stuff away many miles, and then, may be, bring it back again, here were offers for it, and very fair ones, just as it stood in the ground. The same man wanted 20 dozen ears of sweet corn per day, and offered to go to the field and take it himself if I would let him have it at 8 cts. a dozen. While I write, another call has been made for sweet corn, and three men have gone over our whole field. Each man takes two rows; and as they pick it off it is all tossed into the row where the central man walks. A boy follows him with a couple of baskets, gathers it up, and puts it in the wagon; and as soon as the corn was loaded up it was sold. I recognize it as an answer to our prayers, and I thank God for having sent us these customers; yet bear in mind, dear friends, that God could not consistently have answered this prayer unless we had first done our part by having nice corn, nice celery, etc.*

The celery was banked up and nicely bleached clear to the tops. The corn was on ground that was carefully prepared and well manured. Those who had a taste of it wanted more; and so it must be through all our work. There is no excellence without great labor. He who expects God to listen to his prayers must be consistent, and do his part toward making it consistent for God to *answer* his prayers. I do not wish to have you understand by the above that we are now making money by market gardening. Our daily receipts pay for all our help, and some more. But about all that we can say is, that here and there are glimpses of sunshine, and pretty fair indications that we shall ultimately make our work a success financially. The following chapter will serve, perhaps, to make it a little plainer as to how it is to be done.

CHAPTER XXII.

He becometh poor that dealeth with a slack hand; but the hand of the diligent maketh rich.—PROV. 10:4.

No doubt some of the friends who have read thus far in my book will conclude that I am trying to teach some things which I do not understand very well myself. Well, some such thoughts as these were in my own mind a couple of weeks ago, and I therefore concluded that, before going any further, I would invest some money in visiting the most successful market-gardeners of the world. As our good friend A. N. Cole, whom I have mentioned here before as the father of the "New Agriculture; or, the Waters Led Captive," claims to have some of the most productive land on the face of the earth, I concluded to pay him a visit also. I thought I would visit father Cole first, and then go afterward to see the most successful market-gardeners, that I might be able to judge how much he has accomplished at his home on the hillside.

Toward the close of the 26th day of July it was my fortune to look upon said hillside.

---

*A postal card is handed me while I am reading the proof of this page. It is as follows:

Wellington, Ohio, Aug. 10, 1886.

Please ship us four barrels best cabbage. Those you sent were fine; let this shipment be as good.

BOWLBY & HALL.

A few more such orders, and our whole crop of cabbages will be under control. After seeing them spoiling on our hands, can you understand that the above postal is a glimpse of sunshine—yes, sunshine among such commonplace things as a field of cabbages—the sunshine of God's love to his children, and to all who look to him in their troubles and wants?

By the way, round about the town of Wellsville, Allegany Co., N. Y., there are a great many hillsides, and some of them are pretty long hillsides, as well as pretty steep. Father Cole's garden is, some of it, located on ground so steep that it would be difficult for a horse to work it; accordingly it is mostly worked by hand. One of the first things I noticed were springs at the base of the hill —not natural springs, but *artificial* springs. Water was running from four of them at the time of my visit, and the four together made quite a little rill that passes along by the roadside. He informed me that, during the most severe droughts of the present season, some water was all the time coming from these artificial springs. He has just been making a larger reservoir at the upper edge of his five acres, and pretty well near the summit of the hill. This reservoir is to catch enough rain water so as to afford a constant supply to the covered trenches below it from one rainfall to another—or, at least, that is the theory; and I found water standing in the trench while I was there. Now, it occurred to me that this water, instead of passing along near the surface, would sink down into the gravelly soil and go straight into the hill, without watering the plants at all. Father Cole says, however, that this is a mistake. There is very seldom a hillside found so porous that the water runs straight down into the earth, instead of passing slowly near the surface, to the bottom of the slope. Although there had been quite a hard rain only a few days previous to my visit, no gullies and no avenues where the water had ever run over the surface of the earth were visible anywhere over his covered reservoirs.

It would be impossible to mention the long pleasant chats we had during the 24 hours I remained. Father Cole has been studying on this subject more or less since the time he was ten years old. His mind was first drawn to it by a paragraph in Morse's Physical Geography, under the head of "China." The statement is to the effect that the Chinese have for ages excelled in agriculture. They build large reservoirs on the summits of the hills, to catch rain water, and this rain water is allowed to pass slowly downward over successive terraces, so as to irrigate the vegetation from the summit of the hill to the valley below. Well, during these years that have passed, friend Cole has been a deep and diligent student of nature. Here is one of his theories: When the country was new, and our hills and mountains were covered with forests, the surface of the ground was protected by a carpet of leaves. When the rain falls on these leaves it is arrested until it can sink slowly into the earth, watering the roots of the trees, because these leaves hold pretty much if not quite all the water that falls on level plats on the summits of our hills, or even on high ground. The water from these rainfalls accumulates in the shape of bogs, morasses, or wet, swampy pieces of ground. From these wet elevated places, the water slowly descends until it strikes an impervious subsoil of clay, or, as is often the case, a rocky formation over which it flows, dropping over one shelf after another until it comes out of the hill in the form of springs. Man now steps in and clears off the forest. In many places in York State the hills were denuded, simply to sell the timber for firewood to the railroad companies during the time they ran their locomotives by wood instead of coal. After the forests were gone, the leaf-supply was stopped; and in a few years the ground became bare, so that it was cut up and gullied by each heavy rain. The rainfall in this case, instead of going into the ground, washes away the vegetable mold and vegetable soil, and carries it into the creeks. A clover sod might do something toward preventing this great damage and loss to the farmer; but clover sods are the exception, not the rule. The recent rage for tile drainage now comes in (draining off these wet spots), striking another blow at our hillside springs, besides going still further and damaging our wells. This reminds me that Prof. Cook remarked, recently, that he was *afraid* of the results of tile drainage. In his own neighborhood they had been congratulating themselves on draining off a wet piece of marsh that stood on elevated ground. But about as soon as they had the work nicely accomplished, the wells, one after another, in that vicinity, began to dry up and fail. It seemed to me at the time it could not be possible that our wells should be dependent on such marshy places and stagnant pools; but Prof. Cook gave it as his belief that they were. Father Cole, to convince me by an object-lesson, asked me if I could stand a tramp of a mile or two over the hills. Of course, I could. You, my friends, will know that, even if father Cole didn't. First we visited a beautiful soft-water spring, where water enough was running out of the end of the wooden trough, I should think, to fill a two-inch auger-hole.

"Now, my friend," said my teacher, "I

will show you just where that spring water comes from; nay, further: I will take you along the surface of the ground over its path from where we are now, to its fountain-head."

Of course, I wanted to know how he could follow the mountain stream where it was far under ground, through the hills. Said I, "Are you going to take a hazel-bush or peach-tree crotch, and make it bend down when you go over the subterranean rivulet?"

I wish you could have seen the old gentleman as he stopped and turned around and looked me full in the face, to give emphasis to his remarks.

"Mr. Root, unprincipled men who have, by accident, found the same law that I have discovered, have for ages made this innocent crotched stick an excuse for swindling the community. It is a big humbug and a swindle. The crotched stick does not help them a particle, but they use it only for an excuse to get money, and to blind the people. See."

We were going up through the forest, in a little sink of ground, where water comes down from the hills during very wet weather.

"Our underground brook is beneath our feet."

"But how do you know?" I asked.

"I know by the lay of the land, and I have proved it over and over again by digging down until I found the stream; but I can convince you in a few moments, without digging down."

We were now in the dense woods, far up in the hills, and the ground was becoming so damp that occasionally a drop of water hung on the under side of the shelving rocks. By and by it dripped from one stone to another; further on, and it trickled; and still further it was a little rivulet; further still, and we found a level sunken spot on the summit of the hill. Beautiful ferns and mosses grew here; and at one spot the water stood like a tiny lake.

"There," said my guide, "is the fountain-head of our spring. Put in tiles here, take away the water, and you have a few acres of beautiful ground, until you have exhausted the vegetable mold and decayed leaves on the surface of the ground, but—*our spring is gone.*"

I was glad to tell friend Cole, just about at this point, that I could tell him something also. Hundreds of loads of moss, or sphagnum, were at our feet, and yet he had never made any use of it for his "New Agriculture." Now then: Instead of using tile-drains to let this water off from this swamp I have described, or from thousands of other just such swamps, father Cole would let the water be where it is, simply dropping it below the surface in trenches filled with stone, shingling over these trenches, and having all the benefit of the rich soil you would get by tile drainage, or the *still further* benefit of letting the plants extend their roots down into the water. With the tile drainage you run the water with all possible speed down the hill into the river, and it is lost. With the "New Agriculture" you drop it down a foot or more and keep it to serve you during severe droughts when they come, and to water all the ground below it, clear down to the lowermost valleys. Do you see the magnitude of his undertaking?

Let me depart from the subject of agriculture a little to tell you something else that may be done. The town of Wellsville, at the foot of these hills, has a printing-office, the presses of which are run by a water-motor. This water-motor is not much larger than a good-sized water-*melon.*

"Friend Cole," said I, "how high up is the fountain-head that supplies this water-motor?"

"One hundred and ninety-six feet."

Indeed, with *196 feet fall* it is no wonder that that little motor, fed by a quarter-inch pipe, runs the printing-office. Now, father Cole's idea is, plenty of water falls on these hilltops (providing, of course, we husband the melting snows of winter as well as the summer rains) not only to perfectly irrigate all the cultivated land, but to run water-motors enough to *supersede steam.* Over father Cole's mantlepiece hangs a life-sized picture of Horace Greeley. Well, I took friend Cole to task a little, because of his extravagant claims (superseding steam, for instance, as above).

"Why, Mr. Root," said he, "there are possibilities growing out of this 'New Agriculture,' so wonderful that I did not dare to put them in my book."

One of these possibilities has something to do with the picture of our good friend Horace Greeley. Mr. Greeley visited California, as you may remember, and one especial hobby of his was that of irrigating the Great American Desert. Perhaps many of you are aware that it is now actually being done, and that America won't have any "American Desert" at all after a while, if we keep on. Well, Horace Greeley visited and looked upon the great mammoth redwood-trees of California. Not very far away from these great trees he noticed a river that ran into the ground and disappeared, something the way they do in the region of Mammoth Cave. When he got home he confided to friend Cole that it was his honest opinion that those trees were nothing more than common redwoods; that their great size was not owing to the species at all, but to the simple fact of having a subterranean stream under their roots, 10, 20, or may be even 40 feet down, where they drank both winter and summer, to their hearts' content, like the cucumber-vines in the barrel that friend Cole had when he was a boy.

Well, how about the five acres? how about the wonderful crops? how about making the steep and barren hillsides the choicest grounds for market-gardening?

To tell the truth, I was *somewhat* disappointed in the crops on that hillside. A great portion of it was devoted to strawberries, and the plants were really wonderful—larger than any thing I have ever seen in the way of strawberry-plants before. It is, however, well known that the strawberry luxuriates in plenty of water. The raspberries were about such as we have here at home—I think no better; but it should be remarked, that they have had a terrible drought this season, and the ground where they stand has had but little manure. I saw plum-trees loaded with beautiful plums, and found no trace of the curculio. Friend Cole thinks this is owing to his reservoirs of water beneath the trees; but I can not quite understand how it should banish the curculio. His quince-trees are covered with beautiful large fruit. His peas, which I saw in all stages of growth, from those just breaking ground to those just ready to pick, were equal to any I ever saw; but I believe considerable manure was used with them. His potatoes were fair; but the yield where we dug some for dinner was not extraordinary. They were not nearly ripe, however. He has used very little manure — nothing like what market-gardeners use; and in view of this his achievement is certainly wonderful. Near the house an iron pipe comes right out of the side hill. By opening a valve this gives a stream of water at any time—the water coming from the covered reservoirs. It seems to me that great results are to be attained by pumping liquid manure into the upper reservoirs; and if the sewage from a village, town, or city, could be thrown into these reservoirs, I think something wonderful might be accomplished. Rank-growing vegetation would consume and eat up all the filth, in my opinion.

After leaving friend Cole's I started for the market-gardens in the vicinity of Boston. As the newpapers have given us glowing accounts of the work of Mr. Rawson, at Arlington, in the suburbs of Boston, this was my first point; and for once in the world I was abundantly satisfied. I have mentioned before, that it is only *once in a great while* that I see plants make a growth to satisfy me. At Arlington, every thing grew under the high-pressure principle. The ground is a dark sandy loam, near the seacoast; but manure has been put on it year after year to such an extent that many of the grounds seem more like a barnyard than a field; in fact, the smell of ammonia can be perceived, even in passing along the streets. Market gardening seems to be a matter of course with everybody near Arlington. Elegant residences line the streets on either side. Well, at the back of these residences, and often between them, vegetable-gardens were always seen; rows of celery, long enough to satisfy even friend Terry; Henderson's Early-Summer cabbage, with heads so large it would seem a good man is needed to lift even one of them; and the most interesting part of it all to me is, that every foot of ground produces something — not only a plant, but a *prodigious* plant. In Arlington there are no fences, except, indeed, the tight board fences made to keep off prevailing cold winds, and these are not put up as boundaries, nor to keep out intruders, but simply for the purpose before mentioned; therefore I found nothing to hinder my going in and out among the vegetables wherever I chose; in fact, well-beaten wagon-tracks passed into the fields and gardens every now and then, for the purpose of carrying manure and bringing out the produce. As I passed along the street I caught a glimpse of a plant showing wonderful luxuriance, and one which I thought was new to me. A wagon-road passed through at one side of the grounds of this beautiful residence, so I followed it; and when I stood among the plants I found they were simply egg-plants—egg-plants certainly a yard high, and more than a yard across. There was perhaps half an acre of them; and every single specimen on that half-acre was a wonder. The same is true of early sweet corn, heads of lettuce, rows of celery, hills of squashes, etc. They have not yet arrived at such perfection as to have a prodigious head of cabbage exactly like its neighbor on every spot where a cabbage is planted, but they come pretty near it. Great wagons were in the fields loading up these wonderful cabbages. The cabbages were planted four feet apart, and yet the leaves covered the ground so completely that not even a wheelbarrow could be passed between the rows. Accordingly they have an odd sort of a wheelbarrow without any wheel. Instead of having a man at one end and a wheel at the other, they have a man at each end, and on this arrangement the cabbages are carried to the road alongside of the patch.

On the next page I give you a cut which illustrates very well the appearance of the market-gardens around Arlington. The cut was furnished me by the Planet Jr. folks, and was made to advertise their implements; but you can overlook the implements, and you have a very good idea of the Arlington market-gardens.

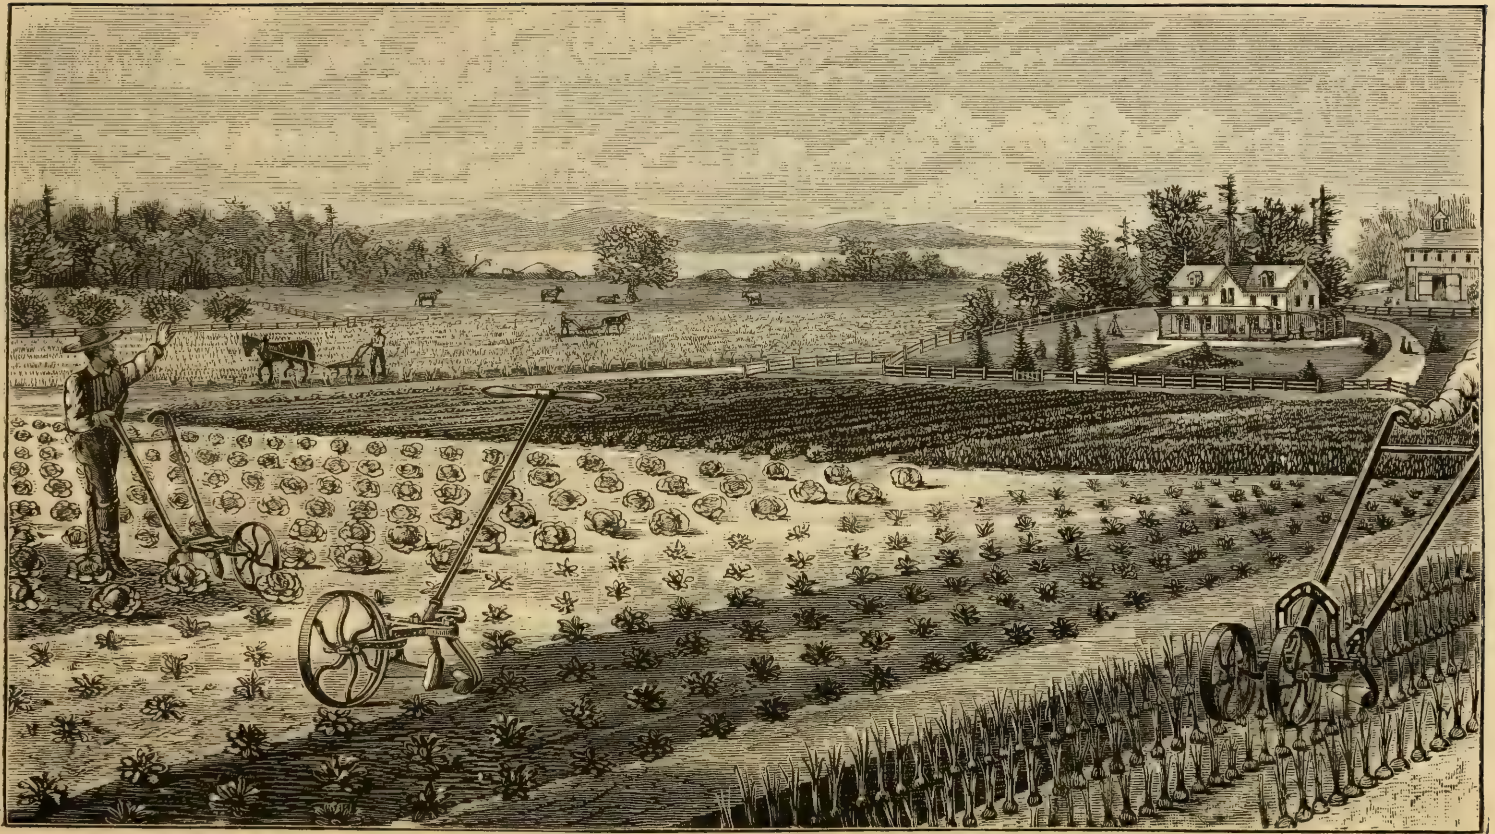
Everybody seems to be very friendly and pleasant in Arlington. In going in and out among the shrubbery, in my inquisitive way, I frequently passed by the occupants of these fine places. While I was examining the egg-plants, a young lady eyed me curiously; but when I explained that I was attracted by the wonderful growth of their beautiful plants, she invited me to make myself at home, and examine any thing that I was curious about. At one point I was attracted by a beautiful flower-garden on one side of the road that passed into the grounds, while across the track were rows of beets in all stages of development. Some of the beets were just breaking through the surface of the ground. A rod or two further they were two or three inches high; still further, nearly fit for market; and finally there were long rows ready to pull. The seed had been sown at different times, so as to give the effect of rising in steps — one step above another, so that, after one sowing was marketed, the next came right after it, and so on. Now, the flower-garden was beautiful; but this little field of beets I think was one of the most beautiful sights I have ever beheld in my life. Of course, hand-weeding is required where every inch of ground is cropped so closely; and in two different places I saw women from the old countries down on their knees pulling out the weeds. I like to pull weeds where the ground is as mellow as it was there, and so I stooped down and pulled weeds a while just to see what fun it was. It had rained the night before, and the weeds came out so easily that it *was* just fun. Who would not like to do gardening with such a soil as they have in Arlington? Well, I reluctantly passed by the beets. Perhaps I should add, that not a weed is to be seen, except among seedlings just coming up. When they get older, the ground is kept almost absolutely clean by the use of scuffle-hoes and similar tools.

Further down I met a man at work on the iron pipes used for irrigation. At Arlington irrigation is used whenever necessity demands it. If it rains, well and good; and if it does not rain, they run water between the plants in the furrows. With celery, a deep, narrow channel is plowed, within about one foot of the roots. Water is taken to the highest point in the rows, and allowed to descend both ways. I explained to the man at work at the pipes that I was attracted by the beauty of their grounds. He bade me welcome, and regretted that he hadn't time to show me around; but he said, "Father is over there in the field; I think he would be glad to talk with you."

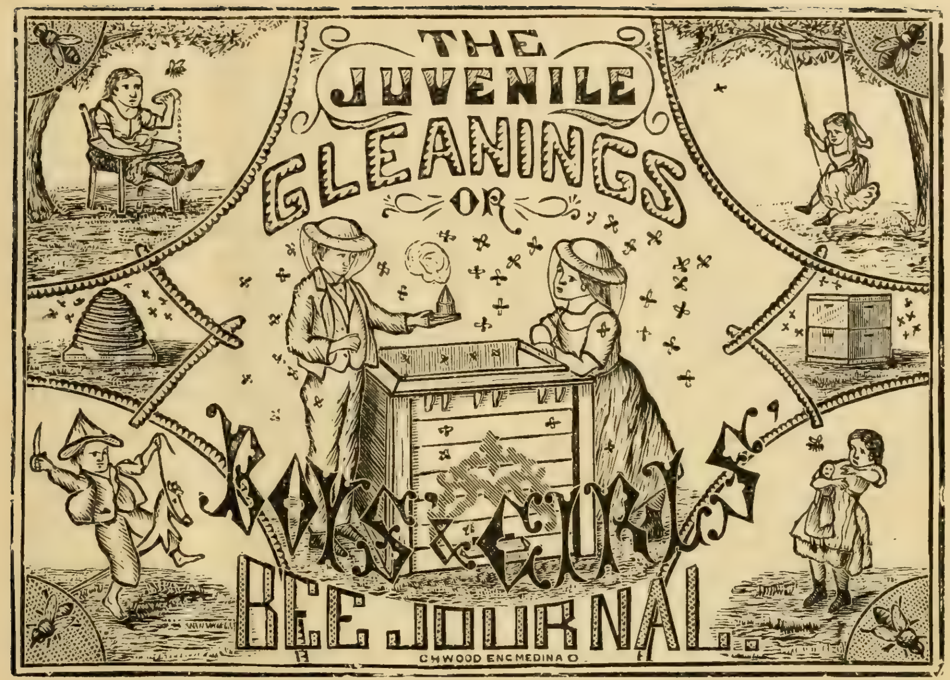
As I came near the old gentleman, I discovered he had a hoe about twice as wide as any we use. The blade, however, was quite narrow. Well, in this soft soil, with such a hoe, even the old gentleman could cut up weeds very rapidly. I found him to be quite aged — so old that his voice trembled quite perceptibly when he spoke. He seemed pleased to find me so much interested, and to know that I was from Ohio. He said, when he was a boy he too wanted to go to Ohio; but it was then away off in the wilderness, and he found that all the money he could rake and scrape together would but just take him there; and then if he didn't happen to like the far wilderness he wouldn't have any money to get back with, when he decided to stay and make garden on the very patch of land where we were standing. He was one of the pioneers in Arlington market gardening. We passed a field of early sweet corn. It was a wonder to me, for every hill had just so many stalks; each stalk was just so high, and had just so many ears on it, and the quantity of ears was so great that the stalks were bending over—each hill toward its neighbor, and each ear seemed to be plump and full, just like every neighboring ear. I expressed surprise, and asked him how many years he had been cultivating that kind of corn, for I naturally thought it must be some new-fangled wonderful yielder. I was a little surprised when he replied, "Nigh on to forty year."

As this chapter is getting pretty long, and as I gleaned a good many things that I want to tell you of in that talk, I think I shall have to reserve the rest for another chapter.

To be continued Sept. 15.



MARKET GARDENING—A SKETCH SHOWING THE WAY THE GARDENS LOOK AT ARLINGTON, MASS.



He that is faithful in that which is least, is faithful also in much.—LUKE 16:10.

MYSELF AND MY NEIGHBORS.

Who is my neighbor?—LUKE 10: 29.

IT was toward evening, just after a beautiful summer shower, that I was on the street-cars in the beautiful town of Arlington, in the northern suburbs of Boston, Mass. The whole place was almost a garden of Eden to me, on account of the vegetable-gardens that spread out on every hand. I had succeeded in finding just the spot that I had for so many years longed for—the spot where gardening is conducted up to the highest standard of intelligence; for it was just outside the limits of the great city that some of the Massachusetts people entitle the "Hub of the Universe." I felt as if I could have walked the whole thirteen miles to the city; but it would have taken too long a time, therefore I stepped aboard of a bright, new, spacious, and airy street-car, such as they have in the suburbs of cities. All at once a vision sprang up before us, so bright and beautiful I almost wondered if it could be real. A florist had arranged, on a beautiful lawn that sloped toward the street, figures of wondrous beauty, all made by planting different-hued coleuses. The recent shower had washed every particle of dust from the beautiful foliage, and the colors flamed out like those of a rainbow. The thought instantly sprang up into my mind, "A painting in which the colors are done by the finger of God."

A good many things contributed to make me happy that July evening. The residences along either side of the street were most beautiful; and glimpses of long rows of celery-plants contrasted with rows of different kinds of lettuce between them; then rows of other vegetables, as they flashed from the open spaces between the dwellings, which were quite a good distance apart, all contributed toward making me feel as if I had been almost transported to some fairy land.

Just as the work of the florist passed from view, a pair of spirited ponies came up from behind us on the other side, with a light, graceful, and fantastic carriage. The horses were a pair that might please the eye of any lover of the horse kind. The buggy might also call forth expressions of wonder and delight, it was so unique. The occupants were a couple of young ladies; and at first glance one would be inclined to pronounce them people of rare intelligence, and from the higher circles in life. They found acquaintances on the street-car, so they drove alongside while they chatted. My eyes first fixed themselves on the horses, then on the carriage, and finally on the occupants. I had been gazing in dazed wonder, almost, at the coleus-bed, and now I sat silent while I gazed for a brief moment at my neighbors opposite me in the carriage. Yes, I think they were my neighbors, even if they were beautiful — yes, wondrously beautiful. Jesus called our attention to the way in which God has arrayed the lilies of the field so that even Solomon in all his glory was not arrayed like one of them. Now, if God has given beautiful forms and colors to the floral and vegetable world—yes, even to the different forms of animal life (the horses at my side) is it any thing wonderful or strange that, for some all-wise purpose, he has now and then clothed the human form divine with wondrous beauty? And when this beauty is accompanied by unusual intelligence, ought we not to pause and wonder, as well as give him thanks? Is it wrong to admire beauty? Surely not, providing that, while we admire, no trace of any feeling springs up that will in the least transgress the command, "Thou shalt not covet." Beauty is a dangerous gift, and so is wealth; and, my friends, let us pray that God may help us so to rear our children that they may safely be intrusted with wealth as well as beauty; that both sexes may consider all these gifts as coming from him, and be enabled to use them for his honor and his glory, and to lay them at the Savior's feet. I did not want to seem rude, so of course I was bound in courtesy to give these new neighbors of mine only a passing glance. They were utter strangers to me, and I do not think any thought entered my mind of wishing for even an acquaintance. They moved in one sphere of life and I in another. God wishes me to perform my allotted work as he wishes them with their beautiful turnout to perform their allotted work in life. It was not in my province to recognize their existence by word or action, unless by the brief glance I told you of; but it *was* in my province to be working for the Master, even at that very moment, and among these very neighbors, too, whom I had found so far away from my own home. Do you ask why? Listen:

While these thoughts were passing in my mind, the street-car stopped. As I glanced toward the platform I guessed the neighbors who stood there were a trio of young mothers with their home treasures. There were three of the mothers, and they had three or four of these treasures apiece; and said treasures were all jubilant at the idea of riding on a street-car. They had got on their Sunday best, and were sweet and clean and bright and happy. As there were but few passengers, each little one was permitted to have a seat and plenty of room to feel happy. As they took their places I gave them a welcome, and remarked that there were almost enough to start a Sunday-school. I could at once see by the looks that were exchanged how many of our passengers were interested in Sunday-school work. The car stops again, and a big lady looks with dismay at the prospect of no seat because they are all occupied by the prattling juveniles. The conductor finally remarks, "Here, you youngsters will have to stand up, some of you." Three pairs of fat chubby legs slid off to make room for the lady. I supposed she would, of course, take two of them in her lap while she made room for the third; but she did nothing of the sort. Even the sad and disappointed faces that were occasionally turned up toward her made no impression on her hard heart. Finally a curly-headed little boy about the size of Huber began to cry because he could not sit down. His mother by my side had one child already in her lap, and so I proposed to take him. She said he was quite bashful, and she was afraid he would not let me. I felt sure, however, I could make myself agreeable, and I did; and by the time he was contentedly sitting on my knee, some other passenger took the hint and took one, and then the big lady volunteered to hold the remaining one. The little fellow was not so easily mollified. He sat on the extreme edge of the lady's knee, and hung his head in a sort of pout. Once in a while he cautiously turned his head enough to get a brief glimpse of said lady's face. It did not seem to reassure him, however, very much.

The shades of night are now dropping over us, and the little one has laid his curly head over on my shoulder, and gone to sleep. For fear he may take cold, the mother throws a light shawl about him. Her accent indicated German origin; and as I glanced from the little one's black curly head to the mother's curly head, almost like it, I became satisfied that at least part of the group had African blood in their veins. I was perhaps holding to my breast a little curly-pated boy-baby with negro blood in his veins. Well, what did it matter? Even if the parents *have* at some time in their lives done wrong, surely there was no wrong in this little one's heart, and who could think of blaming him for the existing state of affairs? My little friends, what Scripture text do you think came into my mind? "Suffer little children to come unto me, and forbid them not, for of such is the kingdom of heaven," Jesus said. He did not say a word about white children, Indian children, or negro children; and if *he* did not, why should I? and I decided in a moment that I was doing the work he had planned for me to do, and I felt happy in doing it.

Two days before, during the stage-ride from Lawson, Cattaraugus Co., N. Y., to Versailles, I passed through what is called the Indian Reservation. Many thousand Indians of different tribes from the State of New York have a tract of land allotted to them. They have farms, cultivate the soil, and raise crops; they also have schools and churches. When I was stopping at the station, a wagonload of them came to the store to trade, bringing in red raspberries picked in the woods and fields. They were intelligent, and looked and acted very much like white men and women. The young mothers had their little ones along with them. The children were dressed prettily, and their mothers seemed as anxious to have them behave themselves with propriety as any of our white mothers. The loungers around the village store said hard and uncharitable things about these people, especially of the mothers; but I am sure it is certainly not *all* true. My heart warmed toward the little ones, and I longed to see them brought into the Sunday-schools, and taught of Jesus their great friend. The driver told us that many of the older people still hold to their pagan superstitions, and that some of them still kept up the time-honored ceremony of something about burning a white dog. He said the only hope seemed to be in educating the children. He added, also, that depraved and dissolute white *men* were doing more harm in forcing themselves among them than the U. S. government and Christian people could do good. In our text the question is asked, "Who is my neighbor?" Now, I can answer for myself, that all these of whom I have been speaking are *my* neighbors. When Jesus said, "Thou shalt love thy neighbor as thyself," I am sure he meant that *I* at least should understand him to mean not only the Indians, but the negroes also; and it thrills my heart to take a good strong man of either race by the hand, and to welcome him as a brother in Christ Jesus. While I regard them as brothers, and long to help them, and to lead them to the Savior, I think it wise and just that there should not be intermingling of the races; but for all that, He who has said, "They shall be my people, and I will be their God," I am sure meant to include all humanity, of whatever clime or parentage.

THE SOLAR WAX-EXTRACTOR.

HOW TO MAKE ONE AT A SMALL COST, AS MADE BY A JUVENILE.

ON page 587 of GLEANINGS for July 15, Ernest requested me to give a description of my solar wax-extractor. I made mine small, as I have but few colonies, and consequently but little wax to extract. Each little scrap of comb can be thrown in, and very quickly made into wax, with no danger of worms bothering. I tried cooking an egg in March, but I left it in too long, not being used to cooking, and I haven't tried it since, as I have been so busy. It was cooked "too much done." To make an extractor, any one who can handle tools can make one at a cost not to exceed 20 or 25 cents.

Use half-inch stuff. First get out two pieces, 6x10½ inches, for sides; two pieces, 6x7½ in., for ends; two pieces, 8½x10½ in., for cover and bottom. Make a frame or sash 8½x10½, outside measure, to hold a pane of 8x10 window glass; this is the size that I used. Also make a frame 9x7 to nail the tin to that forms the basket that holds the comb—one piece of tagger's tin, 8½x10½, to nail to inside of cover for a reflector, and another piece 7½x9½ to nail to the 7x9 frame, letting the middle sag down so as to hold the comb when thrown in. Perforate this with ⅛-inch holes to let the wax run through. Drive eight 2-inch wire nails for the frame to rest on, about half way down the inside of the box, and put a square tin pan in the bottom to catch the wax. The sash holding the glass lies flat on the box, and the cover shuts down on top of that. Strips of leather, ½ inch wide, for hinges, make it easy to raise either the cover or glass, or both, at a time; and a hook on the sash and one on the cover, and a staple in the box, make it easy to fasten. When neatly painted it makes a nice little ornament, and will pay for itself in a short time.

I have taken about 48 lbs. of nice comb honey in one-pound sections from my best colony, besides one new swarm, and more honey to come off yet.

FRED W. CRANSTON.

Woodstock, Ohio, July 20, 1886.

We are very much obliged to you for your very clear description of how to make a cheap solar wax-extractor. No doubt the one you made will do as good work as the larger and higher-priced one illustrated in GLEANINGS some months ago, though it will not melt as large a quantity at a time. I do not know but that I would prefer the smaller one if I wished only to melt up little scraps and bits of wax such as accumulate in the apiary. It is more portable, and costs considerably less, and, better than all, the juveniles can make it. ERNEST.

HUNTING BEE-TREES.

PROOF-READING, AGAIN.

WE insert the following letter just as our little friend "elizzebuth" wrote it—pure and simple. To correct the mistakes would spoil its originality of style, and I think our little friends will have no trouble in making out the story. If the little folks wish, they can count the number of misspelled words and wrong use of capitals. There are other mistakes of a different nature, but you had better not "tackle" them. This will be good practice, and will help you to write correctly.

Father takes gleanings and i see in it where i can i Be lieve earn a Book By righting to you something about Bees. i think it is something new any way. pap ses it is any way; why papa you no is a grate Bee hunter. he went out yesterday to look for Bees and he found too sworms in one tree. the first sworm was a bout 16 feet from the ground, and then they was a division and then there was a nother hollow and it had another sworm in it; i was with him when he cut it. he thought it was an old Bee tree and we would get lots of honey But it was not. it was Both young sworms and one of the sworms was the little Black Bee and the other highest sworm was the larg Big italion and when he got the tree down and split open why the Bees Both mixed up together. well i asked pap if he was a going to put them all in one hive and he sed he was not if he could find the queens Both. well he looked around and seperated the bees till he found one queen and it was the little black queen. well he hived one sorm then he sed he must take them home before he could hive any more Be cause they was enough left yet to make a nother good soworm. well he took that sworm home and he told me to stay here till he would come back and for me to smoke the Beese and Bother them so they could not huddle to gether to git ready to leave till he come Back. well i don so he was not long gon he had not very far to go. well when he came back why it was about 12 oClock and he went to work to see wether he couldnt find the other queen he hunted a while and found her. well he ses lisey i found her. well i went to see her Be cause i had seen the other and i wanted to see what difference they was. well they was a Big difference she was i do Believe twised as Big and she was yallow queen. well now to hive them. well he done that very quick and it was a average sworm pap sed. well he had not more than got them in the hive till a long comes a nother Big swarm and we could not keep them out of the hive they lit on the hive and pap tried to keep them out But all was in vain they was Bound to go in. well they went in and they filled the gum purtey near to the Brim. well he took them home and put them on a stand and the next morning he looked under the hive and found his i talion queen ded and he was vext a Bout it and now the Bees are working and appeare to Be doing well. he ses he is a going to get a nother italion queen. ELIZZEBUTH.

Thank you, "elizzebuth." I am sure no one will doubt that you were an eye-witness, as we call them, of all that you report for the press. I will say for your encouragement, that your letter is no worse than the average juvenile letters. With our present system of spelling it is a wonder that the little folks do as well as they do. ERNEST.

JAPANESE BOYS AND GIRLS.

BY ONE WHO HAS BEEN AMONG THEM.

MR. ROOT:—After considerable wandering we have settled down to a quiet country home in a small town. The seminary which I attended in Reading will be removed here next autumn, when I shall attend it again.

Since coming here my brother thought he would like to keep bees; but as he has had no experience whatever in that line, could you please recommend a book for him to read, or give him a little advice how to go about starting? He is very anxious to keep bees, but I don't think he has ever been in an apiary or seen much about bees.

My thoughts often revert to Japan, and I think of the jolly times the boys and girls there are having during this season. About a month ago was the time for their temple festivities; and though June is the month for general wet weather, regardless of rain they celebrate their religious holidays with great zeal. Great carts drawn by oxen, and sometimes men, are festooned with various paper decorations in the form of fringes and scenery; and Japanese idols, with hideous faces, are taken through the streets. A band with drums, bamboo fifes, and violins, is usually found on the cart, and by its music (?) draws crowds of eager children who shout at the top of their voices, all together making a very noisy procession. Huge casks of wine, profusely decorated, or small temples are borne on men's shoulders through the streets, preceded by priests, who ask alms as they pass. Every one, in whatever circumstances he may be, is expected to contribute something, and also to be dressed in a new suit of clothes. The Christians often get into difficulty in that way, and the house of one of our converts was damaged considerably because he did not give any money to the priests. The little boys procure smaller casks, and carry them about in a wild manner, trying as best they can to imitate their drunken seniors by loud talking and foolish gestures.

Large, fierce-looking wooden dragon-heads, with long draperies of coarse green cotton, are sometimes taken through the city. They, too, are followed by long processions of men, women, and children, some of the latter finding employment in fanning the "dragons" with paper fans or tufts of feathers or hair. You can imagine that the youngsters enjoy these exciting times. But a far pleasanter way, to us, is practiced about the middle of July, on the evening of the second Saturday after the Fourth, when the government has public fireworks displayed on the river S—— running through Tokio. On this occasion many boats full of people assemble on the river; other persons watch the works from the tea-houses on its banks, while the streets are crowded with the poorer classes. The fireworks are well worth expending a little money on. They appear in various beautiful shapes, and are brilliantly illumined. The lookers-on seem to appreciate them fully, for loud shouts of applause, which can be heard for several miles, follow every especially attractive form.

ADA M. KRECKER.

Fredericksburg, Pa., July 20, 1886.

JUVENILE·DEPARTMENT

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from $1.00 to $1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

THE last time. I told you how a bee talks and scolds *folks*; but how do you suppose they talk to each other? This is a question that big folks have tried to solve, and I don't think they really know to a certainty yet. But bees do talk among themselves somehow or other—perhaps not talk, exactly. but they make themselves understood. For instance, a bee has just found a great chunk of honey in the kitchen. After filling himself up full he goes home; and when he comes back he will bring a lot of others, and these others in turn will tell the rest of the bees, until by and by the whole colony, if there is honey enough, will become wild, and finally the whole apiary. Now, how do the bees tell each other that there is something awful nice over there in Jones's kitchen, and that they can get the ill-gotten sweets without the sweat of their little brows? I want you little folks to tell me how they manage to tell each other. Some of the big folks say that they cross their feelers (those kind o' horn-like things that stick out of the bee's head), and that, having done that, they seem to understand. Did you ever see a young bee come in the hive with his first load of pollen or honey? How he will wag his little body in the center of a circle of bees! He acts just as though he were tickled all over, like your little puppy dog when he wags his tail so hard as to shake his whole self. Why do you suppose the bee should make such a fuss? The big bee-men tell us that the bee has just returned with his first load of honey, and that he wants every bee to know it. If I am not mistaken, old bees are guilty of such nonsense. Now, isn't it possible that the old bees, by this "wiggy-waggy" motion tell their mates that there is lots of honey over in Jones's kitchen? Perhaps I am mistaken; but suppose, if you have an observatory hive (if you do not have one you had better get one), you take one or two bees from said hive and put them into a glass-covered box where there is a little chunk of honey. Mary and Johnnie are to watch the bees, one on each side of the hive. In the mean time you are to carry the bees you have caught, some little distance away. When the bees have become pretty well filled with honey you are to dust a little flour over them and let them loose. They will, of course, go right back to their hive, where Johnnie and Mary are watching, and who are to watch these two dusted bees as they come in, and to note how they behave. In some way or other, probably by their peculiar actions, the two bees will induce others to go back with them. Then Johnnie and Mary are to watch them closely and see how they behave.

How many Johnnies and Marys are we to have report for the next JUVENILE GLEANINGS upon this point? It may be that it is too hard a task to perform; but if you succeed well I will send you a nice present of some kind. ERNEST.

A MOUSE DESTROYS THREE SWARMS.

My uncle put some of his bees in a house, and a mouse got in and killed three swarms and carried four quarts of seed corn into the hive. I intend, if I live, to help Uncle Henry with the bees, and hope to learn something more about them.

Hornby, N. Y. GRACE HAVEN.

WHO WANTS SOME CACTUS-BLOSSOMS?

I walk 2½ miles to school, barefoot. Sometimes I get cactus-briers in my feet. The cactus has pretty blossoms—some red and some yellow. If anybody wants any, I will send some for cloth enough to make me or Rhoda (my baby-sister) a dress.

ZELLA H. WRIGHT, age 7.

New Helena, Custer Co., Neb., July 10, 1886.

HOW TO MAKE HONEY GINGER-SNAPS.

I live with my aunt and uncle, who keep bees. They have 71 colonies and 16 nuclei. We have taken off 3000 lbs. of honey, 300 lbs. to take off yet. We bake ginger-snaps with honey. We like it better than molasses. We use honey in making jams and in canning fruits. I will give the ginger-snap recipe: 2 cups of honey; 1 cup of sugar; 1 cup of butter or lard; 1 teaspoonful of soda; 1 teaspoonful of cloves; 1 teaspoonful of cinnamon; 1 teaspoonful of pepper; 1 teaspoonful of ginger. Boil all together five minutes; stir up thick with flour; roll thin, and bake.

I read about a solar extractor. We have one.

NETTIE BRECKBILL.

Kirkwood, Warren Co., Ill., July 20, 1886.

HOW TO HATCH CHICKENS.

I saw that you were having trouble in batching your Brahma eggs. Did you keep the eggs moist enough? Mamma makes her nests by putting dirt about three inches deep in the box, or by digging up a turf. Turn it over and scrape out a hole in the center, and turn it over in the box, and you have the place for the eggs. Now dampen this, and it stays several days, and holds the heat that is necessary to hatch the eggs. Our lettuce and cabbage grow so fast in the garden that mamma said she thought that even Mr. Root would be satisfied. JESSIE S. SMYLIE, age 10.

Caseyville, Lincoln Co., Miss.

HIVING A SWARM OF BEES.

We have 20 stands of bees. The first one came out May 12. We hived it, and on the next day it came out and flew off. We followed it, and it went about a mile. It went into a beech-tree. We cut the tree down, and got the bees in a box and brought them home. We put them in a hive, and gave them a frame of brood. They did well, and made about 25 lbs. of honey above, and on July 1st it cast a large swarm.

HARRY S. GREENFIELD, age 13.

Somerville, Butler Co., O., July 17, 1886.

Did you give the bees a frame of brood when they were first hived? Remember, it is the *unsealed* brood, not that which is capped over, which you are to give to swarms just hived. ERNEST.

CUTTING OUT CELLS TO PREVENT SECOND SWARMS.

Papa's 9 swarms of bees have increased to 20. He took off over 100 pounds of honey yesterday. He did not intend to let them swarm more than once apiece. One colony sent out a second swarm on the eighth day after the first came out. The other colony papa cut out the queens-cells on the seventh day after the swarm came out, and he found some of the queens out then; and in another he found three hatched on the seventh day; and he expected they would swarm again; but the next morning he found two of the queens dead in front of the hive. Besides these, three colonies have been left queenless by cutting out all the queen-cells but one, and that would die in the cells when full grown. CLARA LINDSEY.

Harford, Susq. Co., Pa., June 30, 1886.

The plan of cutting out all the queen-cells but one to prevent second swarms is quite generally practiced, and, as a rule, I believe the remaining cell hatches, though as in your case it sometimes fails to do so.

ERNEST.

WHAT SHALL BE DONE IN A CASE OF SEVERE STINGING?

In the fall of 1884, when my uncle was feeding his bees for winter, a heavy-laden bee which had "stolen the march" on my aunt by getting into the kitchen and taking a gorge of syrup was picked up off the floor by one of my baby-cousins, a boy one year old. The bee stung him on the fore-finger of his left hand. His finger, hand, and arm swelled alarmingly, nor did the swelling end there; for in about twenty minutes his whole body swelled and was covered with white spots. The mucous lining of his nose was so much swollen that he was compelled to breathe through his mouth. My aunt was not a little alarmed. Uncle picked him up in his arms, and carried him as fast as he could to a neighbor's house where they gave him plenty of whisky, and in half an hour the worst symptoms had disappeared. Uncle is a strong temperance man, and does not want either the stinging or the cure repeated too often, and wishes to know if poultices of mashed onions applied to the arm-pits in case of severe bee-poisoning would not be as sure a remedy as alcohol taken internally.

Wm. Joseph Miller, age 14.

Hornings Mills, Ont., Can.

It would seem that the whisky saved the child's life, though it is possible he might have recovered without it. It is said to be an antidote for rattlesnake bites; and if the poison of the snake is similar to that of the sting, no doubt the whisky should be given, by all means, when the life of the patient is endangered. By no manner of means would I use the liquor under other circumstances. As regards the other remedies, I can not answer. Perhaps some physician who is thoroughly temperance in his views could give us light; but please bear in mind that we do not want remedies for ordinary stings where no danger is apprehended.

Ernest.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

A GOOD REPORT FOR CATNIP AS A HONEY-PLANT.

THIS plant, *Nepeta cataria*, is found extensively in the woods and waste places. Here, on the banks of the Ohio River, it has been spreading to an advantage for three or four years. After the white-clover season was past, the bees worked strong on catnip, and continue to do so at present. Many of the unfinished sections, and also the spare room in the brood-chambers, have been filled with honey made from this plant. Even the nuclei send out their "honest workers" to gather a few drops of this abundant nectar, and they are building up. Thus, much of the trouble of feeding weak colonies is now saved, and there is less danger of their being robbed. The bees work on catnip from early morning until almost dark. Through the heat of the day they are found on it, especially if the catnip is in the more shaded parts of the pastures. When the hot days of late summer come on, the plants which are protected from the sun thrive better than the others. Probably if cultivated, catnip would yield considerably more than it now does. Yet, as it is, we are satisfied. As every one knows, catnip is not an injurious weed. One can hardly find a yard or garden without having a few plants. The honey made from catnip appears to be equal to that produced by white clover; and from the fact that catnip remains long in bloom, apiarists should at least save all the plants they may find around them, and give it a trial. In June, 1885, we ordered an Italian queen from you; she has proven to be of fine quality. Ernest Danglade.

Vevay, Ind., July 28, 1886.

WHY DON'T THEY START QUEEN-CELLS?

I have a queenless colony, caused by destroying all the queen-cells but one (to prevent afterswarms), and that failed to hatch. I gave them a frame of eggs, but they have not started any queen-cells. Was it because they are waiting for the dead queen-cell to hatch? They have been queenless two or three weeks. Should I have destroyed the dead queen-cell when I got them the frame of eggs? I know they are queenless, because they have no brood nor eggs in the combs. The combs are full of pollen and honey. If I give them a queen, will the bees clean the pollen out so the queen can lay?

Nokesville, Va., July 8, 1886. W. T. Allen.

A colony of bees will, once in a while, fail to start queen-cells, when it is a little hard to decide why. In such cases we think it best to give them a reinforcement of young bees in the way of a frame of hatching brood. If this frame contains unsealed larvæ, they will very seldom fail to start queen-cells on it, unless they have something in the hive that they look to as a queen. Workers will always prepare a place in almost any comb fit for the queen to lay in, even if they have to remove both pollen and honey.

IS WAX EVER ADULTERATED WITH CORN MEAL?

On page 543, Gleanings for July 1, second column, in reply to D. J. Spencer, on the subject of brittle wax, you say some of your specimens seemed about like Indian meal. I think if you had put it to a test you would have found it was largely composed of Indian meal. Friend Lake had a similar lot, and he proved it was Indian meal, so you see there is cheating by even our vaunted bee-men. Is there no way such rascals can be ferreted out and brought to justice? In Lake's case he was unable to, having previously mixed the different lots together. Yellow Indian corn ground fine can readily be mixed with wax to a considerable extent without detection, so far as sight goes. Of course, it will render the wax brittle and destroy its ductility and tenacity—two very important qualities needed in comb-building. You are in for exposing scoundrels, so suppose you ferret out corn-meal scoundrels, and expose them. C. Garwood.

Baltimore, Md., July 6, 1886.

The wax referred to was not adulterated with corn meal, for it could be melted, every bit of it, into a liquid. It would, however, assume the granular form again as soon as it commenced to cool.

HOW TO MAKE BEES WORK IN SECTIONS.

On p. 570, July Gleanings, Mr. J. M. Tucker asks: "How shall I make my bees work in the sections?" I will give my own views in reply to that question, my views not being theoretical, but based on actual experiments. Any attempt to "*make* bees work in sections" will prove a failure; for while they can, to a certain extent, be led, they can't be driven at all.

The advocates of reversing frames claim that, by so doing, they place the brood above the gathered honey, and the bees then carry it at once into sections. While this is true, it is far from being economical, as the honey must be handled several times in order to place it where it should have been stored originally. It is desirable, then, to do away with this extra labor, which can easily be done, and thus save our bees many steps, and the loss that is always occasioned by moving stores from one location to another. The key to the whole mystery is the spacing of frames. Let the combs in the brood-chamber be just ⅞ inch thick, and spaced just a bee-space apart, then nothing will be sealed up below but brood, if ample room for stores is given in the sections above. All that Mr.

Tucker needs to do is to follow the above rule, and he will have no further trouble. J. E. POND, JR.

Foxboro, Mass., July 28, 1886.

NATIVE BEES OF FLORIDA NOT LAZY.

On page 534, July 1, Mr. C. Moorhouse writes: "The native bees are extremely lazy," and you index the article, "Bees of Florida Lazy." Last year was a bad year for honey, yet I had a natural swarm hived about the middle of March that had filled three stories (30 frames) by the first of June. No combs or foundation was given them. This year the same colony had the second story solid with sealed honey June first, and a crate of 27 sections nearly full. The sections were taken off June 27th, nicely sealed, as fine in quality of work as any man ever saw. They will average 1¼ lbs. each.

Bees swarmed but little this year. My spring count was 11 strong, 4 weak, in Simplicity, and 2 strong in box hives; increased by natural swarming to 21; extracted during June, 53 gallons, and took off 208 1-lb. sections. This honey can not be excelled. It weighs 12 lbs. to the gallon, and is clear, and very light in color. No, Bro. Root, the little fellows are not lazy. Sometimes there is nothing for them to get, and again the mosquito-hawks are so thick they do not fly; and they fight the ants and the moth-worm, the chickens and the children, and I don't know what all. But I do know that they gather lots of honey. Yes, they do work, and so well that I have about concluded our little native is about as good as the Italian, and that they set a fine example to some people who come down here and talk about the laziness of the natives — too many of whom are like Bro. M.'s Northern queens.

Lavasota, Fla., July, 1886. PHILIPPI.

WHAT TO DO WITH SURPLUS POLLEN.

Please state in next GLEANINGS what you do with combs in the spring that are from one-fourth to two-thirds full of pollen. Do you give them to the bees in brood or surplus chamber, or do you melt them up into wax? I put many such in the brood-chambers last spring, and I find it all there yet, so far as I can judge. H. LARGE.

Whigville, O., July 29, 1886.

Friend L., we never have *surplus* pollen in our locality, for the bees use up all that remains in the combs in rearing brood, and you know brood-rearing is a large part of the business in our apiary. The matter is frequently discussed in our back volumes in regard to the disposal of pollen. I believe the most practical way is to steam the combs by hanging them in a covered wash-boiler until the pollen is so soft it may be thrown out with the extractor.

SMOKE WITHOUT SMOKE; GOOD, AT LEAST FOR NUCLEI.

Take an insect-powder gun (Lyon's I am using), fill half full with crystals of hydrate of chloral; press the bellows. The hydrate of chloral evaporates and saturates the air, and stupefies the bees. I find this more efficient than the English method of saturating the air with vapor of carbolic acid and oil of tar. This latter also can be used in the powder-gun by pouring ten drops of each into the bellows of the gun, saturating the air in the bellows.

Tampa, Fla., July, 1886. J. M. PRICE.

Thanks, friend P., for your suggestion of hydrate of chloral; but is it not much more expensive than smoke? This is going to be the important point. We can not afford any thing that costs very much.

RED-CLOVER QUEENS.

Why should any one make a flourish about "red-clover queens," and advertise them as something wonderful? Our Italians, Holy-Lands, and hybrids, work right along on red clover. I stepped into a 40-acre field one day, and it was full of clover, and covered with bees. There were plenty of black bees there, but I saw none of them on the clover; they were working on a little blue flower. Most of the clover has been cut, and the second crop is coming—also where the wheat was cut the clover now appears. D. F. SAVAGE.

Casky, Ky., July 21, 1886.

Friend S., certain queens are called "red clover" because their progeny seem to have a way of gathering unusual quantities of honey during the red-clover bloom; that is, unusual compared with other colonies of similar strength.

OUR CARP-POND.

I should much like to have a report in next issue of GLEANINGS in regard to your carp-pond. I have seen nothing about it lately. Is it a success?

J. W. MARGRAVE.

Hiawatha, Brown Co., Kan., Aug. 2, 1886.

Friend M., it has not proved to be very much of a success as yet, for the reason that, with the multitude of my duties, I have not given it the attention it should have. For instance, although there are fish in the pond weighing several pounds, we have never tried one of them yet for food. Thirty or forty quite good-sized ones were found last winter on the surface, probably killed by the cold, because the pond was not deep enough. The reason it was not deeper is because muskrats persist in digging holes through the bank. The soil is also of such a nature between the pond and creek that the water slowly oozes out, and the pond gets very low unless we have very frequent rains.

HOW TO MAKE FOUNDATION.

Your article on page 513, "How to Make Foundation," is quite acceptable; and although we have always been very careful about keeping our mills free from every particle of wax, the way to do it best has been another thing; and the way to regulate the temperature of the dipping-tank is another. We have had very hard work to get sheets at all; the wax in the tank will get too cold around the outer edges or side of the tank before it is anywhere near cool enough in the center, and consequently the sheets all crack in the center of the boards, while they stick at the outer edges. Now, in this case we have set the tank on the stove and remelted the outer edges of it again, and it sometimes helps the dipping; but we have never been able to get sheets as thin as they ought to be for sections. Do we have to get the wax the right heat by heating and cooling it in this way? or ought the tank full of melted wax to cool all through alike by just setting it off and letting it set until ready to dip? There is something about the way we manage it that is not just right; and if you can give us some light on the subject it will help us wonderfully. Can we use these same boilers where we have a two-horse engine to furnish steam with? We have had all we could make in this way; but our section fdn. does not *quite* suit us.

Roland Holmes.

Ft. Wayne, Ind., June 28, 1886.

Friend H., if I understand you your whole trouble seems to be that you do not set your tank of melted wax inside a tank containing water, to be kept at a proper temperature by means of a steam-pipe. A very small steam-pipe from any kind of a steam-boiler will enable you to keep the temperature of all your utensils just where you want it. During the past season we have made quite an improvement by keeping all of our wax sheets, when ready to roll, in a large oblong tin vessel of water. A steam-pipe goes into this water; and by opening or closing the valve we can keep the sheets just right, no matter whether the weather is cold or warm.

WEEPING LINDEN FOR HONEY; PROLONGING THE BASSWOOD BLOOM.

I send you to-day by mail from Detroit some flowers of the *weeping linden* (*Tilia alba pendula*). I hope they may reach you in some kind of order, so that you may be able to scent the perfume, which is very delicate and powerful. The tree I have hangs over the sidewalk, and every one almost who passes stops to find where the perfume comes from. The American linden (basswood), blooms here about the middle of June; the English, or European linden, toward the last of June, and the weeping is now in full bloom. The white-leaved European also blooms in July, and the broad-leaved European (*Blatiphylla*) blooms in August. By planting all these varieties, the blossoming of the linden could be extended three months. Of course, some of them are scarce yet; but young trees, one or two years, could be imported cheaply from Europe. I imported both the English and the weeping from England some years ago.

James Dougall.

Windsor, Ont., Canada, July 9, 1886.

TOBACCO COLUMN.

A FRIEND'S INFLUENCE, ALSO A KIND WORD.

The goods arrived on the 26th of April, and in splendid order. I have put the chaff hive together. It is the first of your style I ever saw. I am highly pleased with all the goods. I have a bee-keeping friend (a young man like myself), for whom part of the goods were, who has quit the use of tobacco. Can you send him a smoker? If he begins again, I'll see that you get your money. Thanks for extras in goods.

Alvin L. Heine.

Chandler, Ind., May 5, 1886.

I saw your offer in Gleanings, that any one who quit the use of tobacco you would send him a smoker. If you will send me one, I will never use it again; and if I do I will send you a dollar for the smoker.

O. H. Martin.

Lee, Allegan Co., Mich.

Will you please send me a smoker? I have quit the use of tobacco; and if I ever take it up again I will pay you for the smoker.

W. E. Grindle.

Bluehill, Me., June 28, 1886.

I have been a user of tobacco four years, and have quit its use. If I deserve a smoker, send one; and if I ever use tobacco again I will pay you for it.

Fremont, Mich. William Gould.

Please send Henry Powell a smoker. He has agreed not to use tobacco in any way; and if he will he will pay you for his smoker. He asked me to write to you.

Reese Powell.

Linden, Iowa Co., Wis., June 13, 1886.

I sold a colony of bees to a young man who has been using tobacco. He has quit, and now he wants a smoker; he promises to pay for it if he ever commences to use tobacco again.

F. A. Durrand.

Esdaile, Pierce Co., Wis., May 29, 1886.

HAS COMMENCED THE USE OF TOBACCO, BUT PAYS UP LIKE A MAN.

I herewith send you 50 cts. to pay for a smoker that was presented to me for quitting the use of tobacco. I now have taken to the use of it again, on account of my health.

Anonymous.

June 10, 1886.

I am very sorry, friend A., that you thought it necessary to use tobacco again. Are you *sure* that your health demanded it?

After using tobacco for seven years I have quit. If you think I deserve a smoker, I shall be very thankful; and if I ever use tobacco again I will pay you for the smoker. I am a reader of Gleanings, and I think it is second to none.

Fremont, Mich. Robert Ashcraft.

A NEIGHBOR'S INFLUENCE, AGAIN.

I have a neighbor bee-keeper who has used tobacco for years, and has quit. I told him if he would quit and not use it any more, and promise you so, you would send him a smoker. He told me to send. Now, if he don't stay quit I will pay for the smoker, for I have to take care of his bees, and it is not convenient to carry his smoker; but I think he will stick.

John Barlow.

Sac City, Iowa.

THE DUTY OF A FATHER TOWARD HIS SONS.

The boys here use a great deal of tobacco. My two little ones were using it before I knew it. I have induced both to quit. The youngest is not at home. I did not see your offer, but I see the letters. If E. L. Goodbar is entitled to a "smoker," please send it; and if he ever begins again I will pay.

A. C. Goodbar.

Lonoke, Lonoke Co., Ark., June 7, 1886.

THE USER OF TOBACCO AN UNCONSCIOUS SLAVE.

I wish to say to you and everybody that I have quit the use of tobacco since I commenced taking Gleanings. I have used the weed for 15 years, and little did I know what a slave I was to that poisonous weed till after I quit. Nor does any man, who is in constant use of tobacco, realize what a slave he is until he tries to quit. I find that saying and doing are two different things; and when a person says he is going to quit the use of tobacco, he wants to make up his mind that he has got to exercise some will power. If you think I am entitled to a smoker, send me one; and if I commence the use of tobacco again I will pay you for it.

A. B. Holbrook.

Point Peninsula, Jeff. Co., N. Y., June 3, 1886.

OUR HOMES.

I will be their God, and they shall be my people.—JER. 31:33.

I AM invited to meet a body of bee-men to see the Chapman honey-plant in full bloom in York State; and as it is somewhere near father Cole's "Home on the Hillside" I propose to see the "New Agriculture" also, and so off I start this Monday morning, July 26. My first move is to call at the Town-Hall and be one of the first to cast a vote for the closing of the saloons in Medina. Thank God that I have at length that privilege, as one of his people, as in our text.* Then Maud takes me in the buggy to a station 12 miles away. Maud is getting to be a horse-woman, and handles Meg nicely, even if the *men-folks* have let her run away so many times we feared she was spoiled. Meg went up to a watering-trough; and before I knew it Maud hopped out and let down the check, instead of letting me do it. She explained that Meg would put back her ears and bite at me if I went near her, and so I stayed in the buggy. Meg even *goes* better when Maud has the lines, and I begin to suspect there is a sort of freemason understanding between them. Perhaps Meg means to say by actions, "I have had too many masters; that is why I ran away so many times. I like Maud, and she likes me (she gives me my clover and things), and I want her to handle me." All right! I am quite willing, if you only make the train between you.

We pass through a small town; the storekeepers, grocers, etc., are sitting out on the walk in easy-chairs, waiting for customers. They might be doing worse; but ought any of God's people, in these days of such great possibilities, to be sitting and waiting for *any thing?* Why can't they jump up and push something! Farmers along the road, many of them, seem content to raise the same crops (no better) that they have done year after year. Why, I couldn't live if I were not pushing on to something new, as each season comes around. In regard to waiting for customers—how can great strong men sit and wait? I would a hundred times rather follow a plow or a cultivator than to sit before a store waiting for some one to come to be waited on.

Out of town we find great fields of tobacco. While I admire the soil, and the wonderful vegetable growth these plants are making with their broad green leaves as high as the fence, I can not see how any who call themselves God's people can give their best land, and their *very best manure* in raising a narcotic with which to poison their fellow-men. I know it sometimes brings money; but is *getting money* ever to come before *doing right!*

Maud remarks, that the tobacco-raisers never seem to have nice houses and barns, even if the business *is* profitable.

I bid good-by to Maud (and Meg) just ten minutes before train time, so Meg has held her reputation. It costs $1.25 per day extra to ride in a drawing-room car; but if I don't ride in such car I could not have the nice little table on which I am now writing to you. The roads are full of muddy water, and it is running down in muddy streams, all through Ohio and Pennsylvania, although I have not seen a drop of rain fall. Innumerable gardens flit by us, but nothing in any of them is ahead of our own at Medina, unless it is rutabaga turnips in Pennsylvania. Next year *I* will try raising some so early they may be a yard across in July. Buckwheat is looking finely with the recent rains. Some of it is already in bloom, but not a tobacco-plant is to be seen in the whole country.

Olean, N. Y., is an astonishment and a wonder. Huge oil-tanks, big enough to contain large buildings, cover the summits and sides of the hills, and dot the valley by the hundreds, and may be thousands. Surely this must contain oil enough to light the world; in fact, Olean takes its name from *oleum*, meaning oil.

This oil is one of God's latest and brightest gifts to light up "Our Homes" so beautifully and at so little expense. Does this also mean, "I will be their God and they shall be my people"?

Now the train clatters along part way up the range of hills, and a beautiful valley is spread out before us. Villages, with their clean white churches; shops and stores, and many pretty houses, with well-kept gardens, say again the thought expressed in our little text.

It has been raining, and so the white clothes are, many of them, still on the line, telling of patient, hard-working mothers, and of many little ones to be cared for. God grant the thought in all these homes may be, "They shall be my people."

I am much impressed with the looks of the country and people in the vicinity of Chautauqua; an atmosphere seems to pervade the whole country round about; *i. e.*, "I will be their God, and they shall be my people." Is this the effect of the Sabbath-school gatherings there? The fields are covered with beautiful grain and garden-stuff of all kinds.

The sight of Wellsville, Allegany Co., N. Y., with its beautiful residences and thriving business places, reminds me again of our text; and when I go into the house to sit down at the "Home on the Hillside" (after having explored said *hillside* pretty well) I discover a clean bright fire burning in the grate. As the air is a little bit chilly after the rain, and my feet are somewhat damp from my explorations over the soft soil along the hillside, the warmth seems quite comfortable; and then I discover that it is from natural gas.

"Why, dear friends, is it possible that this is natural gas, and nothing more?" And then I inquired, "And does it really give sufficient heat for the most severe winter temperatures?"

In answer to the question, the good lady of the house simply touches a lever with her foot, near the fireplace, and in a second every thing round about the grate is full of

---

*On my return I learned that our people cast 355 votes for *no* saloons, and only 26 *for* saloons. My friends, have you done as well as that in *your* county-seat?

flame, and the heat pours forth in such a volume that I feel abundantly satisfied it is equal to zero weather. When the fire-bricks back of the grate began to look as if they would soon be red hot, another touch of the lever with the foot and the fire is as gentle in a second as a lamb.

Of course, I was up in the morning before anybody else (as usual), and the roaring of the fire, soon after, in the kitchen stove aroused my curiosity. Yes, they were getting breakfast with natural gas, in the same way; and when the breakfast was cooked, down went the heat instantly; no wood or coal to be lugged in; no ashes to be carried out, no smoke or litter. The stove looked as clean and innocent as if it were standing in a hardware store, nicely blacked up so as to show off to passers-by. This great and wonderful gift has all this while been slumbering in the bowels of old Mother Earth, waiting for the intelligence of man to let it out and do his bidding. Gas-pipes run along the streets of Wellsville, on top of the ground. There is no need of burying them, as the *gas* does not freeze up. "I will be their God, and they shall be my people," came into my mind again, and I wondered if the people in Wellsville and other towns in New York remembered to be thankful for this great blessing. I suppose they think of it after a while just about as we think of the blessings we enjoy in our own homes the world over.

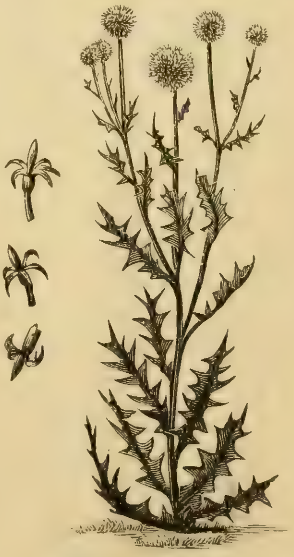
It is July 27th, in the afternoon, and I am waiting for the train at a country store. They said there was not any place to get supper at the station; but I almost always find suppers, and good ones too, and I did this time. One of the young men who clerked at the store invited me to go home with him to supper, if I would put up with what happened to be on hand. We had a very nice supper, including raspberries and cream, and ice-cream for dessert, even in an out-of-the-way country place. The grounds about *this* home were beautiful and tasty, and every thing bore evidence of culture and intelligence inside. I do not know that these people loved God, but I think they do, for many things seemed to say, "And they shall be my people."

Pretty soon a pair of horses drew up to the country store, attached to a somewhat odd-looking wagon. The wagon was sent by friend Chapman to get the bee-men who were to be at his convention the next day. Friend Chapman has a market-garden, so the storekeeper told me, and this was one of his *market-wagons*. Although he is not so much of a market-gardener as he used to be, he has, in years past, made lots of money in the business. I felt glad I had come.

The town of Versailles, Cattaraugus Co., N. Y. is a very pleasant and romantic spot. A great river pours over the rocks, and lulls us to sleep with its roaring. A large flouring-mill, right in the center of business, and many things about the town, reminded me of the village where I lived when a boy. In the evening, boys and girls collected about the postoffice to get the latest news. As a matter of course, the girls were dressed in warm-weather costumes, and some of them were very pretty; and as I listened to their laughing and chatting, I wondered if they, too, were Christians, and if they all went to a young people's prayer-meeting somewhere, every Sunday evening, or may be oftener. Do they ever think of the text I have been thinking of during all this trip? Were they, all of them, even the gayest among them, God's people?

Next morning, with Prof. McLain, our friend L. C. Root, W. T. Falconer, of Jamestown, N. Y., and some others whose names I have forgotten, it was my pleasure to go out among the honey-plants, even before the bees had commenced working. Friend Chapman is a genius, and, like many other geniuses is somewhat eccentric. He has about 175 hives of bees; and although he is progressive enough to have planted fully two acres of the Chapman honey-plant (with enough more that will have blossomed next year to make ten acres) he does not use a movable-comb hive—says he does not want any. Shall I tell you how he markets his honey? Well, he markets it a good deal the way he does garden-stuff. He has it stored in large boxes. He puts these boxes into his wagon, and drives to some town when there are many people on the streets. Then he cuts out his honey in chunks, puts 10 lbs. in one of a lot of cheap tin pans bought for the purpose, and tells the passers-by, "Here, you can have ten pounds of this beautiful nice honey, tin pan and all, for an even dollar." The price is so low, and friend Chapman is such an old hand at the business, that he sells out his whole load in a couple of hours, and goes home with his pocket full of dollars. It is cutting down prices, I know; but it is his way of doing. Well, I was a little incredulous about finding that 175 colonies could gather honey enough from two acres from *any* plant so the bees would store honey in sections. By the way, friend Chapman now uses one-pound sections in place of the large boxes he formerly used; but his hives are still box hives; that is, the brood-apartment is. The honey-plants stand in long rows, and are cultivated like other market-garden stuff the first year. When they first begin to bloom, but little attention is given them. The plant is so hardy that he says the drought killed all the weeds, but did not hurt the plant, and I guess he is right about it. They were growing finely on hard hillside gravel. Friend Chapman has, however, some beautiful land for market gardening, and I think he had the finest patch of cantaloupe muskmelons I ever saw in my life. Although there were several thousand hills, each hill was planted under a box perhaps a foot square and six inches high. Over this box a pane of glass is laid. Melons used to be one of his great specialties, before they brought in so many from the South; but he still makes considerable money from them yet.

At one side of the house, and near the street, I noticed, under a grove of maples, some queer-looking tables painted white. One table was square, with an opening inside, where a workman could stand; the other table was round, with a similar opening. Both tables were surrounded with beautiful maple-trees, evidently planted expressly for the benefit of the tables, for those around the square table were planted at regular distances, in the form of a square; those at the round table in the same way, only they were in the form of a circle. Some of these trees were eight or ten inches in diameter. Friend Chapman remarked, in answer to the question, that these tables were for washing and packing garden-stuff. They did excellent service on this 28th day of July, for our bee-convention. Seats and chairs were arranged for the company. Sections of honey, gathered from the Chapman honey-plant, were on the tables—enough for all. An organ placed on the porch, a little on one side, was well supported by singers of no mean talent; and between the speeches we had good music. The audience was mostly composed of the people from the country round about—friends of Mr. Chapman, and anybody who cared to come, who had heard of his famous honey-plant. Prof. McLain spoke first, and gave us many facts that were new and valuable. He is employed by the U. S. government, as you may know, to investigate and develop whatever is worthy pertaining to bee culture. Our friend L. C. Root also gave us one of his happiest talks, and I felt sorry all through it that we could not have had a shorthand writer to give it in full to our nation of bee-keepers. Your humble servant spoke briefly between the two. He tried to tell the people of God's various gifts to mankind; of the honey to be had for the gathering; of the fruits of the soil, and, later, of the oil and gas, of which I have spoken before, and finally of the new honey-plants that bear honey of such quality and quantity that it will pay to raise them for the honey alone. I spoke of the way in which God seems to call us to exercise our talents and abilities in different fields, and of the peculiar way in which these calls sometimes come. Friend Chapman, with his oddities, feels called upon by some invisible power to use his rare skill in market gardening, toward introducing and disseminating this wonderful new honey-plant. Prof. McLain had told us that its name is *Echinops sphærocephalus*, signifying "round - headed hedgehog," and that the place of its nativity was in the south of France. How should it come here? Even friend Chapman could not tell us, further than that he presumed it was among some specimens he had collected while on a visit to Florida or the Bermuda Islands. While traveling it had been his habit to save specimens of plants. Well, after these dried-up specimens had lain a long time in an old sack in the garret, or some such place, Mrs. Chapman suggested, like a good housewife, that it might as well be thrown away or burned up. Accordingly the sack was turned inside out, and shaken on one corner of the garden. Finally this queer plant came up, and friend Chapman noticed how eager the bees were to visit it. Mr. Hubbard, a neighbor of his, who has been assisting him in his experiments with his honey-plant, told us, in a brief little speech, that he just counted, for an experiment, the bees that visited a single ball of the Chapman honey-plant during just one day. How many bees do you suppose came to this one blossom, or ball of blossoms? Well, *it was 2135.* Of course, an assistant watched the blossom while he got his dinner and supper. To further test the quantity of honey secreted, some paper bags had been tied over the blossoms, two days before the convention. These papers were taken off, and the balls seemed as if they had been dipped in honey —good thick honey too. Since coming home I have tried the same experiment. The honey, as it first oozes from the nectaries, is first thin, like sweetened water; but during 48 hours of our hot July and August days it becomes as thick as honey in the comb. The flavor is a very pure sweet—much like simple syrup, only it has a slight flavor, which we all pronounce very pleasant. I think it will rank equal to white clover or linden. In closing my talk I spoke of all these valuable qualities belonging to this plant, and repeated my text in connection with the thought of God's promises and purposes to us his children. As friend Chapman has expended a good deal of money experimenting with this plant, he prefers to control the sale of the seed—at least for several years. This year it will be offered in packages of half an ounce each for $1.00. No smaller quantity is to be sold. Below we give a cut of it.



CHAPMAN HONEY-PLANT.

In regard to the above plant I submit the following letter from friend Cook:

Dear Mr. Editor:—You will remember that Mr. Chapman, of Versailles, N. Y., exhibited at the Detroit meeting a honey-plant which he said commenced to bloom just at the close of the basswood season, and was of rare excellence as a honey-plant, both as regards quantity and quality of honey which is furnished. Upon examination I found this to be *Echinops sphærocephalus* of Central France. I am indebted to Dr. W. J. Beal for the determination. Through the kindness of Mr. Chapman I secured a number of the plants in the spring. These were set out the last of April; and though the season has been terribly dry they have grown on light sand most vigorously; are magnificent plants, and are loaded with globe-like flower-heads. The plant looks some like a thistle, as we might expect, as it is a composite plant. The flowers opened July 20, and each ball has a great many flowers, each of which must be visited many times a day by the bees; indeed, the flowers are alive with bees from early morn till late in the evening. Surely this thing of beauty is a joy in a double sense. A. J. Cook.

Agricultural College, Mich., July 23, 1886.

The name is from the Greek, *echinops* signifying hedgehog, and the plant is almost exactly like a big thrifty thistle, only it bears round balls, as seen in the engraving. The latter part of the name means "round-headed." Now, if this plant furnished honey right along, day after day, for as many months as the figwort does, it would probably, be ahead of any plant known on the face of the earth. The spider-plant furnishes a larger quantity of nectar, but it is secreted only in the night, and gives us nothing in the daytime. It is also so thin and watery that the amount of saccharine matter is probably not as great as in the Chapman plant The Chapman plant yields honey about 20 days; but by mowing off the tops it can easily be made 20 days later; it is also much hardier than the spider plant, and would probably grow on poor soil where even the figwort would not amount to much. There have been more bees at work on our patch of figwort for the last 60 days than I I ever saw anywhere on the Chapman honey-plant; but the honey is not nearly so thick as that from the latter. It may be a nice point to determine which plant would be most profitable. The Chapman plant will continue to blossom and yield honey for three years, after it is once started. Dr. C. C. Miller, who has experimented considerably, can probably aid us right here; and in any case we can thank God for this new revelation in regard to the possibilities of cultivating plants for honey alone. Of course, friend Chapman's bees were not *all* at work in sections; but colonies having young queens just commencing to lay were storing at a pretty fair rate, and the sections of honey placed on the table for examination were taken from one of these colonies.

The social element at friend Chapman's model bee-keepers' convention was a decided success; and I echoed the thought of our friend L. C. Root, that it would be an excellent thing if we could have more just such informal open-air meetings of bee-keepers. "By this shall ye be known of all men, that ye have love one to another." And how better can we demonstrate to the great Father above that we are trying to look up in the spirit of our text to-day than by showing our good will to each other? "I will be their God, and they shall shall be my people."

The Iowa State Bee-keepers' Association will meet on the Fair-grounds in Des Moines, on Tuesday, Sept. 7, 1886, at 2 P.M., continuing in session during that and the following two or three days A large and substantial tent has been secured, and is now at hand, for the use of the society. Any or all of the 6000 bee keepers of our State are urgently requested to be present and help make the meeting a pleasant and profitable one, and a hearty invitation is extended to all visiting brothers from other States. O. O. Poppleton, Pres.

A. J. Norris, Secretary.

No good thing will God withhold from them that walk uprightly.—Ps. 84: 11.

USING FULL SHEETS OF THIN FOUNDATION FOR SECTIONS.

D. A. Jones says, in the *C. B. J.* for July 28:

> Those who have not used full sheets of section foundation in their sections, should try it and observe the difference in quantity of honey secured. Our experiments have fully convinced us that sections should contain full sheets; and with the beautiful light section foundation we are now making there is no danger of any backbone in the comb honey.

In *Scribner's Magazine* for Nov., 1875, is an interesting article on long life, and from it we quote the following lines:

> Democritus, Pythagoras, and Pliny, trace their length of days to the use of oil without and honey within. Two persons in modern times are mentioned as having lived to the ages of 108 and 116, who, during the last half-century of their lives, for their breakfast took only a little tea sweetened with honey.

REDUCTION IN THE PRICE OF EXTRACTED HONEY.

For the first time in our recollection, we are able to furnish a nice article of extracted honey for 8½ cts. per lb., package included, providing a 58-lb. package be taken at one time; and for two such packages we can make the price only eight cents. We make this discount on two, because two of our square honey-cans ship so nicely in one case. For 10 cases, 20 cans in all (1160 lbs.), we will make the price at only 7½ cts. per lb. This is for the best quality of "Western Reserve" clover honey. For basswood honey, equally good in every respect, the only difference being in flavor, the price will be ½ cent less. Now, then, if honey can not be used at this price, in localities where it is scarce, I shall be much mistaken.

ANOTHER SERIES OF THE WATERBURY WATCHES.

The first gross of series E is now on our hands. While the watches are better made than any heretofore, there has been a reduction in price, so that we can furnish single watches by mail, registered and postpaid, at $2.75; two watches as above, at an even $5.00; five or more watches by express, for $2.20 each. If ordered by mail, in lots of five, add 45 cents for postage and registry; or we will send a watch postpaid, and Gleanings one year, for $3 00; or a watch will be sent free as a premium for 5 subscribers. Of course, Waterbury watches are *liable* to fail, like all other pocket timepieces; and it would be natural to suppose that, if they are furnished at such *extremely* low figures, they could hardly be expected to do as well as watches costing $10.00 or more. We think, however, that the cost of keeping them in repair is, as a rule, much less than with any other pocket timepiece at *any* price.

THE OLD AMERICAN ZINC, AGAIN.

Although the great majority have reported favorably to the perforated zinc of our manufacture, some few have claimed that the queens passed through, and that they preferred the old *American zinc*, made in Chicago, which has the rounded-end holes. For the accommodation of all such, and those who wish to experiment with it, we have purchased a lot of 1000 ft. of this zinc, in sheets 28 x 96 inches, which we can sell @ 12 cts. per ft.; $2.00 per sheet (18⅔ ft.); 5% off for 2 or more sheets; 10% off for 10 or more.

HUMBUGS AND SWINDLES, AND THE "GOLDEN" BEE-HIVE.

On page 480, in our issue for June 15, we published a communication from H. W. Carman, reflecting somewhat on one A. J. Carman. We are informed that both of the gentlemen mentioned there, Hardaway and Carman, are good reliable men. We are glad to know this; but it is not at all surprising that good and reliable men have been drawn into investing in a patent-right bee-hive. Many of our older readers will remember that N. C. Mitchell's strong plan of operations used to be to induce a minister of the gospel, or some professional man, into becoming one of his agents, and then he would straightway get out his advertisements, bolstering up his bad name by having some good man's name coupled with it.

Moral.—Be careful how you let your good name suffer by being linked with any thing disreputable.

THOMAS HORN.

Mr. Horn has been filling orders, to some extent at least, since our last issue, for we have had reports from three or four, to the effect that they had received their bees or queens. A still larger number, however, complain that he has done nothing, and does not answer letters. In one case, where he wrote positively that the bees had been shipped, the express agent at his place declares that no such shipment was made at all. He also fails to meet his promises in regard to the payment of money. When we received Mr. Horn's advertisement we had what we considered satisfactory reference and evidence that he was a straight man; but as soon as we had reason to think he was not acting in an honorable way we refused to continue his advertisement, and promptly gave the public notice. Perhaps we may gain a moral from the whole matter something like this: Do not be in a hurry to send very much money to those who start up suddenly, and promise great things in their advertisements, such as prepaying express charges, etc. Better pay a little more, and deal with those who are old and well established in business.

GOODS NEAR YOUR HOME, AT A REDUCTION FROM REGULAR PRICE.

We have the following lot of goods at the places named, for which we want customers. Now, it is altogether likely that there is some one located not very far from where these goods are who will be needing just such articles, especially if he can get them a little lower than the regular price, and doesn't have to pay much freight charges on them. In hopes that there are such persons, we append a list of the articles for sale, giving the present value of the goods and the amount we will take for each lot entire. We give a number to each lot, and the name of the place where they are being held, subject to our order. Remember, they are all perfect goods, just as fresh and new as if shipped from here. Remember, also, that at the price we offer them we can not break lots; each lot must go entire. In making your orders, please give the number of the lot as well as the articles contained in it, and thus help us to avoid mistakes.

No. 1.	Aplington, Iowa.	Ten 2-story portico hives, complete, in flat, for comb honey, including m. c. frames, wide frames, sections, separators, thin fdn. for sec., 7 lbs. brood fdn., and enamel sheets. The lot foots up to $25.30. We will sell it complete for	$22 00
No 2.	Union City, Ind.	13 combined shipping and honey crates flat; 99 tin separators for above crates; 26 pieces glass for above crates; 10 metal cornered brood-frames in flat. Present value, $4.50; will sell for	4 00
No. 3.	Clay City, Ill.	3000 sections, one piece, V groove, 4¼ x 4¼ x 2 in. wide. Present value, $12 00; will sell for	10.50
No. 4.	St. Joseph, Mo.	10 Simp. hives, made to take crosswise Simp. frames, of No. 1 stock boards, in flat, no inside furniture. Present price, $6.16; will sell for	5 00
No. 5.	St. Paul, Mo.	28 48-lb. shipping and retailing cases, in flat, without glass. Worth $5 04; will sell at	4 80
No. 6.	Lock's Mills, Maine	One roll poultry netting, 4 ft. wide, 150 ft. long; 2 in. mesh; No. 19 wire. Regularly sold for $6.09; will take $5.80 for it.	
No. 7.	Nassau, N. Y.	200 wide frames, for 8 1-lb. sections, in flat. Worth $4 00; will sell for	3 75
No. 8.	Riverside, N. J.	750 1-lb. 7-to-foot sections. Worth $3.00; will sell for	2 75
No. 9.	North Walton, N. Y.	100 metal-cornered frames, in flat. Present value, $2.50; will sell for	2 50
No. 10.	Poughkeepsie, N. Y.	100 1-lb. honey-tumblers. Present value, $3.00; will sell for	2.75
No. 11.	East Otto, N. Y.	1000 1-lb. 1-piece 7-to foot sections. Value, $4.00; will sell for	3.75
No. 12	Caribou, Maine.	900 sections, 4½ x 5 x 1 7/16 wide, open on all four sides. Present value, $4.50; will sell for	3.50
No. 13.	Canal Fulton, Ohio.	Eight chaff hives, complete, for comb honey, in the flat. Present value, $24.00; will sell for	22.00
No. 14.	Delaware, Ohio.	35 bottom boards for Simp. hives; 210 tin separators for combined crates. Present value, $8.75; will sell for	7 50
No. 15.	Foster Brook, Pa.	100 wired m. c. brood-frames, in flat, including wire and tin bars. Present value, $3. 00; will sell for	2.75
No. 16.	Johnson City, Tenn.	One No. 7 honey-extractor, with basket, only 15 in. deep. Present price, $8.00; will sell for	6.00
No. 17.	Cairo, W. Va.	One 2 story Simp. hive, rigged complete for comb honey, and 5 lbs. fdn., ½ thin, for sections, and ½ for L. frames. Present value, $5.25; will sell for	4.75
No. 18.	Elmira, N. Y.	One 2-H. P. engine and boiler complete. This has been used some, but has been put in as good shape as when new. Price of a new one, $175.00; will sell this for	$150.00

OUR OWN APIARY.

FOUL BROOD AGAIN, AND HOW WE ARE HOLDING IT IN CHECK.

From various letters that we have received, and from further experience with the disease, we feel pretty well convinced that we have been fighting the real foul brood, so called. Our friend Milton Hewitt, of Perryopolis, Pa., however, who had some sad experience with a different phase of diseased brood (page 699, 1885), is of the opinion that our colonies are infected with the same disease which attacked his bees. Speaking of the characteristics as observed in this type of affected brood he says:

1. "That the disease is not contagious by contact, or by introduction of bees, honey, comb, brood, etc.

2. "That the infection is transmitted by the fertilization of the queen by a drone from a diseased hive."

He further states, that the removal of said queen, and the introduction of new blood, cures the affected colony.

In regard to this I will say, were this form of the diseased brood present in our own apiary we should expect about one-fourth of our brood-combs fit subjects for the furnace. Whenever we have introduced queens from foul-broody hives into other colonies we have yet discovered no instance where they transmitted the disease. On the contrary, as we should expect with foul brood, the larvæ of said queens are not as yet affected; but we have found, and that to our sorrow, that *honey* from diseased colonies gives the disease. It is a well-known fact, that bees from neighboring colonies intermingle to some extent, and that, in consequence, some little honey would be exchanged. Now, wherever we have found one diseased colony in our apiary we have invariably found four or five other diseased colonies neighboring and adjacent to this one, showing that the disease was transmitted by the honey, and proving the old statement that foul brood is a disease of the honey.

Since our last report, several more cases of foul brood have appeared in our apiary, and the number of diseased combs now cremated in the boiler-furnace is 126. Whenever traces of the disease have developed, the colonies so affected have been treated as described upon pages 610 and 630, just as soon as discovered; no matter whether the colony was so badly diseased as to emit the foul-brood odor at the entrance, or so little affected as to reveal only an occasional diseased cell, the manner of cure was the same.

Some have made an outcry against the seemingly needless and wanton destruction of so many combs. I shall have to reiterate that new frames of foundation are not only cheap but safe; that, while we do not decry the use of salicylic acid as a disinfectant of foul brood, or the trying-out of the affected combs, we *do* know that the absolute cremation and destruction of combs affected by foul brood is sure to prevent the further spread of the disease from said combs. Furthermore we can not afford to run any risks by experimenting upon the more lenient measures recommended for cure, when so many colonies are at stake.

I am glad to say, that, when the apiary was last gone over, no trace of the disease appeared. If it shall not again break out, then we shall feel that we have employed the cheapest way of fighting the disease, and that there is nothing like "nipping it in the bud." But, hold! a prominent bee-keeper and apicultural writer has just written us, expressing his regrets that the dreaded foul brood has at last visited us. He says, "I am very, very sorry to hear that you have foul brood in your apiary, knowing as I do what a terrible thing it is." In spite of all the skill he could bring to bear he has had fully 75 cases during this and the previous season, and, as a matter of course, he has had to discontinue the sale of bees, as we have done. Surely, there are not many crumbs of comfort in this for us. If, however, we shall cure the further ravages of foul brood, and thereby be enabled to instruct our fellow bee-keepers how to detect the presence of the disease, and how to cure it without the usual sacrifice, we shall feel ourselves amply repaid; and instead of a misfortune, a visitation of the all-seeing Providence.

SHALL WE PURCHASE SUGAR OR CHEAP HONEY TO FEED OUR BEES THIS FALL?

This is a question that has been asked many times; and many, no doubt, since this matter of foul brood has come up, have decided in favor of the sugar. As already stated, we feel pretty certain that the disease originated in our apiary from honey that we purchased. We can assign no other reasonable cause. I was talking with a bee-man who made us a visit the other day, and who said that he had intended this fall to buy cheap honey and feed it to his bees; but that, since we had come out so frankly, stating the probable cause, he had decided to feed sugar. No, sir; we may talk about feeding bees their own "pure sweets," the folly of purchasing sugar at the expense of the honey-trade, and all that sort of thing; but if we purchase cheap honey of a doubtful or unknown source, we are running a risk. It is true, we may boil all such honey to kill any possible germs of the latent disease; but that would be attended with some little expense. Of course, if you have honey of your own raising that you know is good, that is another matter; but if you purchase honey to sell again, store it away where the bees can by no possible means get a taste of it.

SENDING FOUL BROOD BY MAIL FOR PURPOSES OF EXAMINATION.

At different times we have had samples of affected brood sent us for our examination, accompanied by a letter of inquiry as to whether the sample was a real case of foul brood. While in our individual case we do not fear any infection to our bees (as immediately after examination we always "hist" it into the boiler-furnace), yet, in the minds of all carefully disposed bee-keepers, we think the practice in general would be condemned. Some one less careful, and not knowing the real danger, might do our fraternity a vast deal of harm. This would apply to the one sending the specimen, as well. If I am correct, Prof. Cook, in his books, has cautioned his readers against sending such samples by mail. If any of you have a great curiosity to *see* and *smell* foul brood, you had better be content with what you can gain from the pens of others less fortunate, or you will think it is a real case where "ignorance is bliss 'tis folly to be wise." ERNEST.

FARM OF 57 ACRES,
AND APIARY OF OVER 100 COLONIES
OF BEES FOR SALE.
15tfdb GEO. A. WRIGHT, GLENWOOD, SUSQ. CO., PA.

FOR SALE.

One Barnes combined circular and scroll saw, size of table, 26x36, including 13 circular saws from 3 to 8 inch; 11 scroll saws; 2 mandrels; one 6 in. emery wheel; 1 cutter-head; 1 saw-set; all in good running order, except some of the saws may want filing. Will sell the above machine with all the attachments for $35.00 cash, delivered on cars, which is about half price.

Address **S. H. WINCHESTER,**
16d **Elmore, Peoria Co., Ill.**

PREPARE FOR WINTER.

We have unequaled facilities for manufacturing the Root chaff hive at a great reduction from ruling prices. Mr. Zeno Doty, Grafton, Neb., writes July 9th, "Your material, make, and price is far better than I can get anywhere else. Send for price list and special prices for this fall. 16tfdb

A. F. STAUFFER & CO., Sterling, Ills.

For Sale. COLONIES, NUCLEI, and QUEENS, AT LOWEST PRICES.

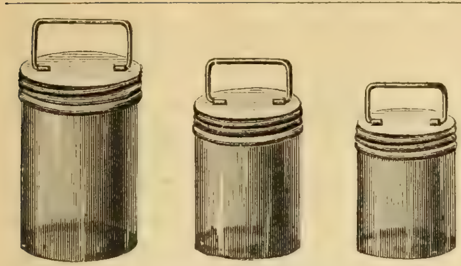
DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.



GLASS

HONEY-PAILS CHEAPER THAN EVER.

In retailing honey, as in selling almost every thing else, there is nothing that pleases customers more, or secures quicker sales, than a good article put up in neat and tasty packages. For extracted honey in small quantities for a "lunch" or "picnic" it seems to me nothing is more handy, or will "take" better than these glass pails. They are made of flint glass, as clear as crystal, so that the customer can readily see just what color the honey is which he is getting. The top screws on securely; and, better than all, it has a handle to carry it by so that you may always have it right side up. Moreover, the manner of attaching this wire handle to the tin cover has been improved by soldering on the tin clip holding the handle, instead of cutting a hole in the cover and bending over the points on the inside. By buying a very large quantity of these pails direct from the manufacturers we are able to offer them to you, in lots of 100 or over, cheaper than we have been able to get them from wholesale glassware men in lots of 1000. Here are our reduced prices, free on board cars at Medina:

	Each	10 rates	100 rates	1000 rates.
½ lb.	5 cts.	40 cts.	$3.50	$32 50
1 "	5 "	45 "	4 00	37.50
1½ "	6 "	55 "	5.00	47.50

These pails are packed 100 in a barrel; and at these close prices we can not give 100 rates on less than 100 of one size, as it would necessitate repacking. **A. I. ROOT, Medina, Ohio.**

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column. 3btfd

---

ATTENTION, BEE-KEEPERS!

Now is the time to Italianize cheap. Having all my orders filled to-date, I will sell fine queens, from my well known strains, at the following very low rates.

2 H. P. ENGINE FOR SALE.

We have at the factory in Elmira, N. Y., a 2 H. P. engine and boiler that has been rigged up exactly as good as new in every respect. It ought to bring full price of a new one, but in order to get it off our hands we offer it for $150.00.

A. I. ROOT, Medina, O.

VERY LOW.

I have a number of selected tested queens which I will sell for one dollar each. These will be fine queens to breed from, all reared this season, and guaranteed to satisfy all. I will also dispose of a few full colonies of pure Italian bees in Sept. and Oct., in new L. hives, at $7.00 each.

16-17d S. F. REED, North Dorchester, N. H.

THE AMERICAN APICULTURIST

Sent one year, and a tested Italian queen, to each subscriber; all for $1.50. Sample copies free.

15tfdb Address HENRY ALLEY, Wenham, Mass.

100 GOLDEN ITALIAN QUEENS.

Cells taken from colonies that have swarmed. Warranted second to none in every respect. Should any prove to have mismated they will be promptly replaced with nice tested ones. I will ship next day after receiving order, if so desired. Price 75 cts. each; per doz., $8.00.

15-16d JAMES WOOD, North Prescott, Mass.

PURE ITALIAN QUEENS.

Tested queens, $1.50 each; untested, 70c each: 3 for $2.00; 5 for $3.00. All bred from a select imported mother. By return mail.

15tfdb D. G. EDMISTON, ADRIAN, LEN. CO., MICH.

HONEY COLUMN.

CITY MARKETS.

ST. LOUIS.—*Honey.*—We quote to-day's market on honey: Comb, choice white clover, 1-lb. sections, 10@12½c; choice white clover in 3-lb. sections, 9@11; other varieties of comb in 1 and 2 lb. sections, 8@10; broken comb, 5@7. Extracted, white clover, in tin cans, 6@7c; same in kegs, 5@6; white clover and other varieties of extracted and strained in bbls., 4@4½. Honey is moving very slowly, at even low prices. There is some demand for low grades for manufacturing purposes.

Beeswax.—Selected yellow, 25c; as it runs, 21@23c.

Aug. 11, 1886. WESTCOTT & HALL,
108 and 110 Market Street, St. Louis, Mo.

CLEVELAND.—*Honey.*—The market still continues slow and well stocked. Choice white 1-lb. sections sell at 14c with an inclination downward; as yet, however, no new honey has been sold at less than 14. New 2-lbs. dull at 12@13. Old stocks are neglected. Extracted, 6@7. *Beeswax*, 25.

Aug. 10, 1886. A. C. KENDEL,
115 Ontario St., Cleveland, Ohio.

DETROIT.—*Honey.*—The market for honey has improved a little since my last quotations. Best white, in one-pound sections, sells at 14c, and some in a small way at 15c. *Beeswax*, firm at 23c.

Aug. 11, 1886. M. H. HUNT,
Bell Branch, Mich.

MILWAUKEE.—*Honey.*—Market for honey is dull, and lower prices will have to be accepted, to sell. We will quote: Choice 1-lb. sections, white, 12@13c; choice 1½ and 2 lb. sections, white, 12@12½. Old, choice, in sections, 10@11. Extracted, choice, in bbls. and kegs, 5@6; same, in tin cans, 6@6½.

Beeswax, 24@25. A. V. BISHOP.
Aug. 11, 1886. 142 W. Water St., Milwaukee, Wis.

KANSAS CITY.—*Honey.*—The receipts of new honey are good, and demand the same. 1-lb. sections, white clover, 13@14; 1-lb. sections, dark, 10@11; 2-lb. sections, white clover, 11@12; 2-lb. sections, dark, 8@10; 2-lb. sections, California, white, 10@11; 2-lb. sections, California dark, 8@9. Extracted white clover, 5@6; dark, 3@4; California, 5@5½; dark, 4.

Beeswax, 20@22. CLEMONS, CLOON & CO.,
Aug. 11, 1886. Cor. 4th and Walnut St's.,
Kansas City, Mo.

BOSTON.—*Honey.*—New 1-lb. sections, 13@15; new 2-lb. sections, 12@14; new extracted, 6@8. *Beeswax*, 25 cents.

BLAKE & RIPLEY,
Aug. 11, 1886. 57 Chatham St., Boston, Mass.

NEW YORK—*Honey.*—There is no change in the honey market; still, there is some old honey on hand, almost unsalable at any price. We are receiving large shipments of California white-sage honey, extracted, in 5-gallon cans, 2 in case, which is sold at from 5@6c per lb. We have not received any new comb honey this far.

Beeswax, a trifle lower. Prime yellow sells at from 22½@24c. THURBER, WHYLAND & CO.,
Aug. 11, 1886. Reade & Hudson Sts., New York.

CINCINNATI.—*Honey.*—No change in the market; demand slow for all kinds and shapes of honey. Prices are nominal. Extracted honey ranges between 3½@7c per lb. on arrival, according to quality, and choice comb honey brings 14@15c in a jobbing way.

Beeswax.—Demand is good, and arrivals are fair. We pay 20c per lb. for good yellow.

Aug. 6, 1886. CHAS. F. MUTH & SON,
S. E. Cor. Freeman and Central Avenues,
Cincinnati, Ohio.

FOR SALE.—I have 400 lbs. of nice white-clover honey in 1-lb. sections, in crates containing 24 sections each, at 13c per lb., crates included, delivered on cars here. Also 50 swarms of bees, 20 in Root's chaff hive, and the rest in Simplicity hives—all very strong. J. D. STEDMAN, Charlestown, Port. Co., O.

FOR SALE.—I have 300 or 400 pounds of choice comb honey, put up in 24-lb. cases, which I will sell for 11c per lb. It is nice and white, raised with separators, and is first class in every respect.
WM. H. STANLEY, Dixon, Lee Co., Ill.

FOR SALE.—2000 lbs. clover honey in 1-lb. sections, large cases at 15c; and in small cases at 16c at our R. R. Station. O. G. JOSENHANS,
Owosso, Shi. Co., Mich.

FOR SALE.—2000 lbs. of nice white-clover and basswood honey in 1-lb. sections, put on board cars here for 13 cts. per lb. C. ABRAHAM,
Fayette, LaFayette Co., Wis.

FOR SALE.—I should like to sell 2000 lbs. of comb honey in one and two lb. sections. I will deliver it on the cars here for 12½ cts. a pound. It is nice white honey. F. ROULO,
Portville, Catt. Co., N. Y.

FOR SALE.—10,000 lbs. of nice white-clover and basswood honey, in one-pound boxes, 48 lbs. in case, delivered on board cars for 12c per lb. by the case, or 11c per lb. in 1000-lb. lots. EZRA BAER,
Dixon, Lee Co., Ill.

FOR SALE.—Friends, I have 1500 lbs. of beautiful honey in one-pound sections, in crates holding 11 and 12 lbs., that I will sell at 12½c per lb.; also extracted honey in 50-lb. kegs at 8 c, delivered on the cars. Cash with order. Reference given if needed.
W. S. DORMAN, Mechanicsville, Iowa.

FOR SALE.—1000 lbs. of white-clover honey, in 1-lb. sections. What am I offered? WM. VANAUKEN,
Woodville, Jeff. Co., N. Y.

FOR SALE.—5 barrels, of 170 lbs. each, one of 250 lbs., of basswood honey, well ripened; also 2 barrels of clover honey of 170 lbs. Will take 6 cents, barrel free, delivered on cars at Lynnville.
W. A. COMPTON, Lynnville, Giles Co., Tenn.

FOR SALE.—I have 1500 lbs. of comb honey for sale, 15 cts. for No. 1, 12 cts. for No. 2.
NELSON DEWEY, Adrian, Lenawee Co., Mich.

FOR SALE.—10 crates of comb honey, containing 36 pounds each, in one-pound sections, ready now.
MARCUS WIGHT, Bedford, Iowa.

FOR SALE.—Still having on hand in Root's beautiful 1-lb. sections some 2000 lbs. of white-clover honey, I offer the same at 14c per lb., packed in Heddon's shipping-cases, and put on board of cars.
JOHN ELLINGER, Hopkins Sta., Allegan Co., Mich.

WANTED.—From 500 to 1000 pounds of white extracted honey. What is your price, delivered at Malone? H. P. LANGDON,
East Constable, Franklin Co., N. Y.

WANTED.—I have a place for a few tons of clover honey, *white;* can pay N. Y. quotations—5c, put up in bbls. of from 300 to 500 pounds each, F. O. B., anywhere in Ohio or this way from there.
F. D. WOOLVER, Munnsville, Madison Co., N. Y.

FOR SALE. PURE ITALIAN Bees & Queens.

Untested queen, $1.00; two or more, 75 cts. each. Tested queens, $2.00 each. Full colonies, in Simplicity hive, with tested queen, from $4.00 to $10.00. Three-frame nuclei, with untested queens, $2.00; with tested, $3.00. For July, August, September, and October, address or call on

Residence, Little Muskingum. BENJ. J. COLE,
16d Marietta, Wash. Co., O.

FOR SALE CHEAP.

Fifty 2-story Simplicity hives, nailed and painted; 100 2-story Simplicity hives in flat, and 10,000 brood-frames. For particulars address
16d O. H. HYATT, Shenandoah, Iowa.

Pure Italian Queens.

I have purchased the entire stock of bees of Mr. L. L. Langstroth. I will sell queens from natural swarming, at 80 cents each, or six for $4.00. Safe arrival guaranteed.

CONVENTION NOTICES.

The annual meeting of the Western Bee-keepers' Association will be held in Pythian Hall, corner of Main and 11th Streets, Kansas City, Mo., Oct. 27, 28, 29, 1886. P. BALDWIN, Sec.

The Willamette-Valley Bee-keepers' Association will meet at the Grange Hall, in McMinnville, Ore., Sept. 21 and 22, 1886. All interested are invited. E. J. HADLEY, Sec.

The Iowa State Bee-keepers' Association will meet on the Fair-grounds in Des Moines, on Tuesday, Sept. 7, 1886, at 2 P.M., continuing in session during that and the following two or three days. A large and substantial tent has been secured, and is now at hand, for the use of the society. Any or all of the 6000 bee-keepers of our State are urgently requested to be present and help make the meeting a pleasant and profitable one, and a hearty invitation is extended to all visiting brothers from other States. O. O. POPPLETON, Pres.
A. J. NORRIS, Secretary.

17-22db Address G. F. ROBB, Gilman, Iowa.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column. 3btfd

A BARGAIN IN HONEY-TUMBLERS.

Among the many cheap packages for retailing extracted honey, the ½-lb. and 1-lb. tin-top glass honey - tumblers hold a prominent place. Though not quite as handy to carry as the glass honey-pails, they are much cheaper, and will be preferred by some. We have at last succeeded in obtaining these direct from the manufacturers, and get jobbers' prices instead of buying them from jobbers, as we have had to do in the past. We can thus offer them to you at the following reduced prices:

½-lb., 3c each; 25c for 10; $2.40 per box of 100; $5.25 per bbl. of 250, or $21.00 per 1000.

1-lb., 3c each; 28c per 10; $2.75 per box of 100; $5.20 per bbl. of 200, or $24.00 per 1000.

Orders for 1000 will be filled direct from the factory in Pittsburgh. You will notice that the tumblers are much cheaper in barrels, as a barrel costs us 35c, and a box of half its size costs 50c.

A. I. ROOT, Medina, Ohio.

CARNIOLAN + QUEENS.

Carniolans are the Gentlest Bees Known,

AND EQUAL TO ANY OTHER RACE FOR WORK.

THE QUEENS ARE THE MOST PROLIFIC.

I offer daughters, of Imported Benton Carniolan queen, raised in my apiary of 40 colonies of pure Carniolan bees, during the remainder of this season, $1.00 each; six, $5.00. Ten cents extra on each queen to Canada, England, Ireland, and South America. **DR. S. W. MORRISON,**
13tfdb **Oxford, Chester Co., Pa.**

Jerseyvile, Ill., July 23, 1886.

Mr. J. T. Wilson, Dear Sir:—The 55 warranted queens I received of you last year were all purely mated except one. The most of the queens were choice, and as good as higher-priced ones, for general purposes. E. ARMSTRONG.

One queen, 75 cts.; 6 for $4.00. Warranted purely mated. Will work as well on red clover as anybody's bees. Will exchange for honey, alsike clover seed, or Poland-China hogs. All queens sent by return mail unless ordered to the contrary.
15d J. T. WILSON, Nicholasville, Ky.

DADANT'S FOUNDATION FACTORY, Wholesale and retail. See advertisement in another column. 3btfd

Vol. XIV. **SEPT. 1, 1886.** **No. 17.**

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00; 10 or more, 75 cts. each. Single Number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent TO ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

NOTES FROM THE BANNER APIARY.

NO. 81.

DISTANCE APART FOR COMBS.

GEO. A. WRIGHT, in the *A. B. J.*, says: "I notice some are having trouble in trying to get the bees to build worker comb. With me this season it has worked like a charm. I hive my swarms on from five to seven frames; the frames are spaced 1¼ inches from center to center. If they are put further apart than this they are sure to build drone-comb."

Perhaps one reason why I have succeeded so well is because my frames have never been further apart than 1⅜ inches. Putting them thus close will not *always* prevent the building of drone-comb, as I have had one-fifth of the comb built drone-comb when the queen was three or more years old. I do not doubt that putting the frames close together *aids* in securing worker-comb.

SHAVINGS FOR SMOKER FUEL.

You mention, Mr. Editor, trying planer shavings *a la* Heddon, in the Clark smoker, and that it was not a success. I wish you would give them a trial in the Bingham—the Doctor. I have both the "Conqueror" and the "Doctor" sizes, and the Doctor works the better. This, filled with shavings, packed down, will smoulder away for hours when not in use—like fire in a bank of sawdust—while a few puffs will bring forth a perfect deluge of smoke. Mr. Heddon tells us how to light the shavings with rotten wood or punk. *I* light it as follows: Put a *small* handful of shavings into the smoker, not all over the bottom, as then the fire is blown *away* from the shavings, and they take fire very slowly; but put them to one side, in such a manner that the bottom is about half covered with shavings. Light a match and carefully set it on end upon the bottom of the smoker, leaning it against the shavings. As the shavings take fire, work the bellows *very* slowly and steadily. As the fire increases, slowly incline the smoker in such a manner that the pile of shavings will gradually "fall over upon the fire," so to speak, and cover the bottom of the smoker. When this handful of shavings is nearly burned into cinders, add another handful of shavings; get these well to burning, then fill up the smoker, and it is ready for business. The trouble in lighting is in adding too many shavings at first, thus smothering the fire before there are sufficient shavings afire to hold the fire. When well started, the fire in the "Doctor" has *never* gone out until it burned out, and brother and I have taken solid comfort this season with our "Doctors," and planer shavings for fuel.

By the way, I believe I never told of a visit that I once made to Mr. Bingham. It was during the State Fair two years ago, that Mr. B. whisked me home with him to stay over night. After being shown through his smoker-factory, and witnessing the care, thought, and attention bestowed upon valves, springs, bellows, fastenings, and other *apparently* trivial matters, and then considering the *grand* "direct-draft" principle, I no longer wonder *why* the Bingham smokers are so far superior to all others.

QUEEN-EXCLUDING HONEY-BOARDS.

Tell Dr. Tinker that I *did* see his honey-board at the Michigan State Fair, but did *not* notice how it was made. The first time I thought of putting strips of zinc in grooves cut in the edges of slats was when Mr. Heddon wrote me last winter, saying that he was going to make some slat honey-boards, and *tack strips of zinc to them*, and he wished for my opinion as to whether to put the zinc under the slats or over them. Quick as a flash came the thought: "Put them in the middle." The spaces between the wooden slats would then be shallower, and less likely to be filled with brace-combs. Before my reply reached Mr. Heddon, it seems that both a student of his and he had conceived of the same idea. Dr. Tinker was, however, the *first* to make public this method of constructing honey-boards; and although others were *original* in discovering the same thing, they have no desire to rob the doctor of the honors that justly belong to him. I have used 20 of these honey-boards this season and I have nothing yet to add to what I have already said. They are *very* satisfactory. By the way, a correspondent suggested to me, some time ago, that he thought the solar wax-extractor would be an excellent place in which to clean honey-boards.

INVERTING HIVES.

I think Mr. Kretchmer is correct in his views in regard to the effect that inverting may have upon queens and queen-cells. I have wondered for some time if inversion did not rob the bees of their *desire* to swarm, and that the *bees* then destroyed the queen-cells.

THAT "EXPLANATION."

I have no desire to again open the discussion of the validity of the "Heddon patent," but *would* like to say a few words in regard to the "explanation" that Mr. Kretchmer was asked to give. When I wrote the article defending Mr. Heddon and his hive, you, Mr. Editor, replied by publishing an article from Mr. Kretchmer in which he unfairly or unwittingly claimed to have invented, used, and patented a hive similar to the Heddon hive. Upon seeing a copy of Mr. K.'s patent, you wrote to him for an *explanation*. Mr. K. seems capable of giving us some valuable ideas; but before again entering these columns, did not common courtesy demand either a retraction, apology, or explanation?

W. Z. HUTCHINSON.

Rogersville, Mich., Aug., 1886.

Friend H., Mr. Kretchmer did promptly send an explanation. The explanation was, however, too lengthy and complicated to be published. It seemed, however, to be reasonable. I forwarded it to friend Heddon, and suggested that we had better let the matter drop. I hope friend K. will excuse me for saying right here, that, several times during the past ten or fifteen years, his explanations have been, to put it mildly, quite unfortunate, to say the least. I published what I did in regard to the effect of inversion on queen-cells, etc., because it seemed to me as if there were a valuable point here that should be investigated.

LETTER FROM NEW SOUTH WALES, AUSTRALIA.

WHAT A WOMAN'S ENERGY AND DETERMINATION WILL DO WHEN HER HEART IS IN THE WORK.

DEAR MR. ROOT:—My brother has sent you a list of things he wants, and has written you, one of his short business-like letters; but I want to write to you about our friends the bees, and I thought you might like to know a little of their doings in far-off New South Wales.

Would you like to have some of my experiences in bee-keeping? For years I have been a lover of bees; but as the greater part of my life was spent in India, where the bees build their combs like a sponge stuck on a stick, I never succeeded in doing much more than reading and treasuring up every scrap I could get hold of about my little friends. When I first came to the colony, scarcely a bee was to be seen anywhere. "Driven out by the moth" was the universal verdict. Even the bush, or forest, as you would call it, was destitute of bees. About four years ago I bought my first swarm, which, to my grief, I found to be queenless. After this I heard of a man who kept bees in common gin-cases, about four miles away; so one fine bright winter's day away my brother and I started (he came only to please me, for he was not a bee-enthusiast then, but he is now). The old farmer gave us a swarm that had not been robbed since the spring. We were so much afraid to trust our newly acquired treasure to any one else, we resolved to carry it home ourselves, much in the same fashion in which the spies carried home the grapes from Eshcol. Well, to make a big story short, we carried home our box of bees and honey over four miles of as hilly a country as you would wish to see, and did not get home till midnight. It weighed over 70 lbs. It was a grand swarm, and I think we deserved it; but, as usual with beginners, we were in too great a hurry, and lost nearly all by increasing too rapidly.

The next was a bad year; but we got some honey, and our bees did not require feeding in the winter.

Last summer the rain failed us altogther, and what honey was gathered was very thick and dark. I saw some take a prize at a show that was more like treacle [cheap molasses.—ED.] than honey. As our space was very limited this year we did not increase more than we could help. Now we have, after giving away some swarms, ten good strong stocks. You will see by my brother's list that we intend going in very extensively for bees this year. I don't think we shall have any difficulty in selling our honey; but if you could see the honey usually sold here I doubt if you would care to touch it. Bees, brood, pollen, moth, grubs, and all, pitched into a bag and hung out in the sun to strain. Those who put this mixture into a bucket, and stand it in a boiler of hot water, and then strain it through at once are considered as rather advanced bee-keepers.

Mr. Garrett, of late of Glenbrook, and ourselves are anxious to establish, as soon as possible, a central depot for the sale of pure extracted and comb honey, and we thought it would be a good idea to combine apiarian requisites with it. As you have so much experience in these things I thought the best thing we could do would be to ask your advice; and, if you agree with us, to ask you the best way to set about it. Think the matter over, Mr. Root, and let us know what you think. We should like to get the things from America, and we should like particularly to get them from you, as you seem to understand the wants of bee-keepers so thoroughly. Mr. Garrett lent me a lot of your GLEANINGS. I have studied them carefully, and I don't think you will think me presumptuous if I say I feel as if I had found a new friend.

I meant to have told you something about bees in Australia, and I have selfishly taken up all the paper with my own affairs. We have one great advantage over English and American bee-keepers—our bees require no wintering; an extra mat or a couple of sheets of newspaper under the cover is all we need.

On the 18th of June (the 21st is our mid-winter day) I opened the hives and found eggs and brood in all stages; again on the 12th of July it was the same with this difference—that the brood was all at the top of the frames, and the honey at the bottom. I think we shall have an early spring and good honey season; and if it please God we hope to do well with our bees this year. Bee culture is beginning to excite some interest here; but still there are plenty of people who think we are quite mad to think of making money by bees.

I have come to the end of my paper, so I must bring this to a close by asking you to see that the things are sent as quickly as possible I am anxious to begin work. We should have sent the month before, with Mr. Garrett's order; but through a misunderstanding it was left behind.

SOPHIE A. BRADLEY.

Campbelltown, N. S. W., July 13, 1886.

My good friend, your description of your first start brought vividly to my mind my experience with my first swarm. It was carried home on a pole between two of us, exactly as you describe; and as it was a hot autumn day the sweat dripped from our faces before we got the hive to its destination; namely, the upper floor of the woodshed. You say you carried your hive four miles, but I believe we carried ours only about one mile.—I should be very glad indeed to give you some practical suggestions in regard to starting a supply-house, but I know too little of your circumstances and surroundings. I would suggest, however, that you invest cautiously, and bend all your energies toward making the bees themselves open a way for a brisk trade. Nothing ever helped me so much to establish a business as pouring tons of honey on to the market, the product of our own apiary. Articles written for your local papers, answering questions and explaining improved bee culture, will greatly help you.—Many thanks for your very kind and encouraging words. It gives me a thrill of pleasure to know that I have made friends, even in far-off lands, by what I have written about bees. May God bless and prosper you in your undertaking, for I am sure it is one that is pleasing in his sight. Perhaps I should explain to our readers that the above letter was accompanied by an order for over $200 worth of supplies.

CAN A QUEEN LAY 3000 EGGS PER DAY?

A. W. OSBURN'S OPINION ON THE SUBJECT.

HOW many bee-keepers are willing to be put on record as saying that it is their candid opinion that they ever owned a queen that laid 3000 eggs a day? For one I am not willing to be put on record as saying any such thing. While for the last ten years I have kept bees in a warm climate, and where it is reasonable to expect the queens to lay as fast as in colder climates, yet I am not going to say that I ever thought that any one queen laid for me 3000 eggs in 24 hours. Let's figure a little: Suppose the queen has got to lay 3000 eggs in 24 hours, how long will that allow her for each egg? According to my figuring she will have 28.8 seconds for each egg; that is, supposing she does not lose any time, which is a wrong supposition; for the time lost in examining cells that have already been laid in, and in traveling over the comb, will reduce the aggregate of her day's work fully one-third (that is, if she is expected to lay 3000 eggs in one day. You or any other bee-keeper can satisfy your minds upon this subject by watching any good prolific queen while she is laying. Hold your watch and see how many eggs she deposits in one minute. I have known them to deposit three in one minute, and then go three minutes and not deposit any; but when there is nothing to disturb them, and the comb is free from pollen, about two eggs a minute is their speed, *while they keep at it;* but they do not keep at it all the time; they stop and have a friendly chat with some worker, or perhaps take a little refreshment, as they go from one comb to another, for no queen fills the full side, or two sides of a comb, before she goes off from it; but the time is going on; and when the 24 hours roll round, if she has deposited 2000 eggs she has, in all probability, done about the best she could.

Now, it will not be out of place here to say some things for the benefit of beginners about the habits of queens while laying (I am speaking now of full colonies that have from 8 to 10 frames). It is supposed by many *beginners*, that, when they put an empty comb in the brood-nest, the queen is going to fill that comb the first thing she does, and that, too, without leaving it. Nothing can be further from the fact, as experience shows. The queen goes from one side of her brood-chamber to the other every 24 hours, or nearly that, examining every comb that has brood in, to fill all cells where bees have been hatched; and if the empty comb comes in her way she puts in it what eggs she has time to, but never to the neglect of the combs where young bees are hatching constantly; for it has always seemed to me that, if there were any one thing that a queen delights in doing more than another, it is to lay in cells that bees have just come out of. A. W. OSBURN.

Havana, Cuba, W. I., Aug. 2, 1886.

Why, friend O., it is not a matter of opinion, but simply a question of figures. From our observations here, a queen will fill one side of an L. frame, and sometimes a part of the other side, in 24 hours. What we mean by "fill" is two-thirds or three-fourths of one side. As queens fill a frame somewhat in the form of a circle, there is generally not over three-fourths of the cells with an egg in. The number of eggs can now be very easily determined by calculating the number of cells to the frame. It is commonly estimated that there are about 25 worker-cells to the square inch. This number per inch would be correct if the cells were square; but as they are hexagonal in form, Cheshire has shown that there are nearly 29 cells to the inch. Taking 28 cells as the basis, we find that, in round numbers, there are about 4000 cells to one side of an L. frame. On the supposition that a queen can fill three-fourths of this number, 3000 as the total number of eggs laid by a queen in a day is about correct. You say you have seen queens lay three eggs a minute; and yet if she lays two a minute, at this rate she will lay very close on to 3000 eggs in 24 hours. You say that she does not keep this rate up. Opening the hive and exposing the queen and frame to the light is apt to break up the normal condition of affairs. Were the hive closed, a good fertile queen on a frame of foundation nearly drawn out ought to be able to fill the frame nearly full in a day; at least, we have had queens do it repeatedly. Bear in mind, that we are talking about what queens *can* lay, not the daily average number per day.

UNFINISHED SECTIONS, ETC.

WHAT TO DO WITH THEM.

IN response to Bro. Stewart, on page 654, I will say that there are two ways to handle unfinished sections of honey. They may be finished by feeding back extracted honey; but most or all who have tried this plan have abandoned it. Our method has been as follows: All combs that are not sufficiently filled and sealed to make a fine appearance on the market, we place in a frame (six at a time), and after uncapping the part that is sealed we sling out the honey which is particularly clean, and place them in storing-cases, to be placed on the hives during the most excessive flow of the following season, when the bees can not build comb fast enough to hold the nectar they can easily gather.

Now about the "bulging" of the combs in these replaced sections. We have suffered this inconvenience, and know the cause and prevention. When you are re-casing the sections of combs, combs of various stages of development, never put thin and thick combs next to each other; neither put the fuller side of one section next to the shallower side of another. Put full sides together, and shallow sides together, and only such sections in any one row as are about equal in comb growth. This is the way we handled the few bulged sections that were left unfinished. With these precautions, bulging is made straighter, rather than crooked, the second year.

We have never had any trouble with pollen getting into the sections because of "contracting," and we have practiced it five years, and are quite sure that we shall continue its practice as long as we produce surplus honey. We are sure we have abundance of pollen here. No, we have never noticed that "reversing" combs tended to the depositing of bee-bread in the sections. During the past three years we have had in use from a few to as many as 6000 reversible frames, and have never yet been able to discover any objection to them, but many advantages instead. We never expect to use other than invertible combs.

We have never yet had a cell of brood "chill" when practicing our method of preventing *after-swarms*, and can not see how any can become chilled if my directions are followed.

Now, friend Root, I consider it my *duty* to offer a public protest against the article in last issue, pages 651-'2, signed E. Kretchmer, wherein he again lays claim to one of the prominent functions of my new hive, patented last Sept.; viz., the use of a brood-chamber divided in two horizontal parts. You will recollect, that, on page 211, Mr. K. claimed to have a patent, No. 67,123, that antedated my invention, and that copies of that patent showed that claim to be untrue, as not a single function of my hive was therein shown. I claim this and the use of half-bee-spaces as prominent parts and parcels of my invention, and hereby respectfully ask all brother bee-keepers to respect my rights in them.

Dowagiac, Mich., Aug., 1886. JAMES HEDDON.

Friend H., our answer to friend Hutchinson covers partly what you say in your last paragraph. We published friend K.'s article because it seemed to suggest or call attention to something of value. Very likely it would have been better to omit the last paragraph of friend K.'s article to which you allude. I do not believe it is best to discuss the question of rights again on these pages.

THE WAX QUESTION, AGAIN.

ARE THERE ANY MISSING LINKS IN HASTY'S EXPERIMENTS, AS RECORDED ON P. 641?

I WAS very much interested in reading friend Hasty's article on the wax question, but it still seems to me that there are some "missing links" in the really wonderful chain of evidence and experiments that he has constructed.

In the first place, how did he ascertain that the swarm, when first hived, had no wax secreted? He says that he thinks they did not have any. Bee-keepers have generally supposed that a colony before swarming always begins secreting or forming wax, or, at least, that a swarm after issuing is provided with quantities of wax scales. If this be true, then how can friend H. estimate the amount of nectar used to form *this* wax? and, also, what proportion of the wax stored during the days of testing was already secreted when the swarm was hived?

Again, on account of the bees being in a wax-secreting condition (allow me to use such a phrase), would they be obliged to draw as heavily upon the nectar already stored, for this secretion, as would an older swarm, just beginning to form comb, as in working in section boxes? He writes, that a colony rearing brood will consume about seven ounces only, during a night. If this is the case, what becomes of the large amount of honey that a swarm of bees contains when the bees leave the parent hive? We all know that the bees gorge themselves before swarming, and I have hived such swarms (which I should judge had fully 2 lbs. of honey in their sacks) after they had been clustered about an hour, and then they did not have much if any honey, and they took nearly 2 lbs. of honey from a feeder, immediately after I had hived them, and this before they had any combs built in which to store this feed. Now, what had become of their first load? They could not have eaten it all simply to satisfy hunger. I have seen bees from new swarms return from the fields with a load of honey, and also with wax scales adhering to them. Who can say but that this wax was secreted while the bees were at work in the fields? and how can we get at the amount of nectar required to form it? It seems to me, that, in order to get *exactly* at this question, as Mr. Hasty would desire, we have got to pursue a different line of investigation, and have *all* points tally more correctly than they seem to in his article.

I would not have you think that I write thus simply for argument's sake; but I believe in this: "If you don't talk you won't say any thing;" and I would say, "If you don't read or write in bee-journals you won't learn much about any thing"—at least, in this line. CHAS. H. SMITH.

Pittsfield, Mass., Aug., 1886.

Friend S., your suggestion, that the bees consume honey while in the fields, for storing wax, is an important one. I do not now remember that I ever saw wax scales on a bee while at work in the fields; but perhaps it is because I was never on the watch for them. I confess I do not see how we can get at the matter with much accuracy while the bees are allowed to fly; and it may also be true that we can not get much accuracy where they are *not* allowed to fly. If so, how shall we decide on this important question?

SALT FOR BEES.

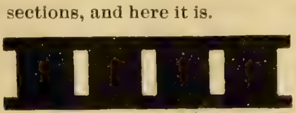
FOSTER'S OPEN-SIDE SECTION.

ON page 502 are two references to my article on salt for bees, as given on page 178. In reply to the first I will say that I have heard that stock that graze near tide-water do not need salt as do those that graze further inland; and if so, it may be the same with bees.

In regard to the second, I can say that, while I have not seen bees "shoulder a lump of salt," I have seen them sucking the damp earth just below a deposit of salt on the points and edges of earth, as referred to in my article on page 178. This, I think, proves *almost* conclusively that it is a strong solution of salt they are after.

SECTIONS OPEN ON ALL SIDES.

I was very much interested in the Book Review, wherein was mentioned Foster's open-side sections (see page 483). Ever since I became acquainted with the open-end section I have felt that it was "the thing;" but in practice I met with difficulties. It seemed to be intended to be used without separators, and, in consequence, with sections both wide and narrow, I had bulged comb, so I have attempted to devise a separator that could be used with open-end sections, and here it is.



TIN SEPARATOR, EXPRESSLY FOR USE IN SECTIONS WITH OPENINGS ALL ROUND.

The slots are intended to match with the edges of the sections, and will enable the bees to have the same free communication that they would have without them. I think the slots in the separators should be about ¾ inch wide, and in the sections somewhat narrower than you make them. Further, I would not fasten the separators to the wide frames, but hang them from the top-bar; then, by detaching them, the bees can be brushed from both sides of the sections instantly. W. H. GREER.

Paris, Tenn., July 19, 1886.

The separator figure above has been many times suggested, and the same, or something quite similar, is in use by different parties. The principal objection is the expense of manufacturing such a separator.

DESTRUCTION OF QUEEN-CELLS BY INVERTING THE BROOD-COMBS.

FRIEND SHUCK GIVES US SOME ADDITIONAL FACTS IN REGARD TO THE MATTER.

SO far as I know, my statement of the fact as to the destruction of queen-cells from their inversion was the first made. I have found, in not less than 150 trials, that the cell, if so far built as to turn downward, will be torn down and destroyed by the bees, if inverted at that time. Also, it will be thus destroyed if inverted at any time from the turning downward of the cell to the final sealing of the same. If inverted after sealing, to within two or three days that the queen is due, the cell shrivels up, sinks into itself, as it were, and is treated precisely as a cell from which the queen has failed to emerge; that is, sometimes it is torn down and sometimes is allowed to remain. In this latter case the young queen seems to have been destroyed by inversion: in the former cases it would seem that the cells and larvæ are destroyed by the bees because they have been inverted. I have found no practical use for the discovery.

It has been suggested, that, when a colony swarms, the parent hive might be inverted, and a new queen run in. This plan would succeed in a majority of cases; but should queen-cells be destroyed in this wholesale way? I think not. Rather save the queen-cells in some suitable way, and then introduce the queen.

Mr. Kretchmer's statement (see p. 651) as to "horizontal" queen-cells is hardly to the point. Such a cell can be inverted only by turning the comb upon its side. None of us are yet reckless enough to try this experiment. Our friend speaks truly when he says, that "many other profitable manipulations can be accomplished without inverting, and that is *alternating*." So can they with invertible frames; but the consumption of time is against the two latter, and in favor of the former. A hive can be inverted in less time than two chambers can be alternated, or the frames handled separately.

Mr. Pond pays his respects to inversion, but doesn't tell *all* the truth. Inversion does place the brood above the stored honey in the brood-nest, and the honey there stored will be carried into the sections (if they are in place); but this is not all. The space thus cleared will be occupied by the queen, and more laborers for the harvest are thus secured; and the *habit* of carrying the honey to the sections is thus established; and if the *habit* is not interfered with by swarming or queenlessness, it will be likely to continue till frost stops the work.

SHAVING THE COMBS TO $\frac{7}{8}$ IN. TO MAKE BEES STORE HONEY ABOVE, A LA POND.

The thin combs so justly praised by Mr. Pond (page 529) are not infallible; and whatever of value attaches to them is perfectly adapted to the invertible system. In fact, I use nine frames during the white-honey harvest in an eight-frame hive, but I remove one frame for the fall harvest so that the combs may be bulged to repletion for winter stores.

The invertible hive and all its appurtenances are as cheap as any non-invertible hive of the same class of material and workmanship, and the time required to manipulate the invertible for the production of honey is not one-fourth the time required for a non-invertible hive. There is the gage, come who may. J. M. SHUCK.

Des Moines, Iowa, Aug., 1886.

A DEFENSE OF THE BLACK BEE.

A REPORT THAT WILL DO CREDIT TO ANY RACE OF BEES.

SEEING Mr. Doolittle's article, in Aug. 15th GLEANINGS, "On the Different Races of Bees," I feel I can not let it pass, especially that part of it which has reference to the black, or brown bee, without standing up and speaking in its defense. What he says about it as a poor honey-gatherer is not true in my experience. I have kept bees for the past 8 years, and have had nothing but blacks, and my returns compare favorably with those of my brother bee-keepers who have Italians. To prove what I say, I will give you some of my experience.

Three years ago was a good honey season in Canada. I had 30 colonies in the spring; 5 were weak and 25 were good. I got 4500 lbs. of honey, of which 1200 lbs. was comb; increased to 80, and the colonies averaged 25 lbs. each for wintering. Is that "from hand to mouth," or "calculating a day or so in advance"? Now for two poor seasons, especially this year: I began with 130; increased to 220; got 7000 lbs. of honey, of which 2400 is comb honey, and they all average 25 lbs. per colony for winter. Is that "from hand to mouth"? Last year was very much like this, when we got about the same per colony. Those of my acquaintances who have Italians get no more per colony than I do. As for the wax-moth, I have never lost a colony from that cause yet, and surely they must resist it, or they would all have been destroyed; and as to their being cross, I find no trouble in handling them. Now, I say that both Italians and blacks have good qualities. It hurts me to hear the bee run down, that has proved such a friend to me. I also see that Mr. Root agrees in every particular with what Mr. D. says. Now, Mr. R., can you say from actual experience that what Mr. D. says about the blacks is true as honey-gatherers?

WM. COLEMAN.

Devizes, Ont., Can., Aug. 26, 1886.

Friend C., I am very glad to hear your good report with common bees; but if you will excuse me, it seems to me it does not strike the point after all. You say you had nothing but blacks; therefore, how do you know that Italians in your hands would not have done a good deal better, even, than the report you give? It is true, you say your neighbors have done no better with Italians; but I suspect that, if your neighbors had only blacks, like yours, they would not have done nearly as well as they have done. I presume you know it is a common thing for one bee-keeper to get good yields of honey every season, while his neighbors around him do little or nothing. It is in the man as well as in the bees. The comparative difference between the Italians and the common bees has been settled for years, with such overwhelming results in favor of the Italians that I hardly think it worth while to open it again. We are glad of your report, however; but I would put it something this way: "Mr. William Coleman, of Devizes, Ontario, Canada, has obtained 7000 lbs. of honey, and increased from 130 to 220 during the past year, and that, too, with only common black bees." I hardly think you will call me prejudiced, because this matter has been discussed over and over for many years.

HOW TO UNITE,

AND MAKE THE BEES STAY IN THEIR NEW LOCATION.

I HAVE just received a card from W. H. Ritter, of North Springfield, Mo., in which he wishes to know how I unite my bees without having trouble; and as it might be of interest to many of your readers I will give you my plan—one that has never failed with me so far, though I can't tell how soon it may. In the first place, I never unite except when they are light, both in bees and honey.

A little before sunset, when the weather is good, I take my smoker and go to the colonies I wish to unite; and by a vigorous smoking and jarring of the hive I cause them to fill themselves with honey. This takes only a few minutes. I then simply pick up the hives and carry them near the hive where I wish them all to remain, open them all up, and, if necessary, give them another dose of smoke; then I shake bees of the colony that stands in the place where I wish the united colony to stand, all or nearly all off the combs in front of their hive, setting their combs in an empty hive close at hand, replacing them with combs from the other colonies, after the bees have been shaken off in front of the same hive. In this way I get the bees thoroughly mixed, so they are all strangers to one another, and I sometimes alternate combs from different hives; but it is not essential—at least, I have not found it so.

Now you will ask me, "How do you get them to stay on the strange stand?" Well, I keep a lookout for a while after uniting (the same evening and next morning); and if any considerable number of bees go back to their old stand I let them buzz around until they get thoroughly frightened at the loss of their home, then I pick up the united colony and carry it around to the place where they formerly stood, and in five minutes I can pick up all the stray bees, then carry the hive back where it belongs, and hardly a bee will go back to his old stand, provided the hives are all taken away so they can not see them. To be successful with the above plan, all the hives should be of one color, and as much alike as possible. By the above plan I united 39 colonies back to 24 in my own yard; and in another yard, about 12 miles from here, belonging to a lady friend, I doubled back from 17 to 7 in the middle of the day, and never stayed an hour to look after them, and she writes me that hardly a bee went back. The proof of the pudding is in the eating; and in this case it has proved excellent. It may be well for me to state, that all the above was done during a dearth of honey, when bees are inclined to be more quarrelsome than at any other time.

M. BROERS.

Gonzales, Texas, Aug. 23, 1886.

Friend B., your plan of uniting colonies and making the bees stay in their new location is very similar to the one we practice here at the Home of the Honey-Bees. Of course, we think *our* way is a little simpler, but the principle underlying both is the same. I have no doubt your plan will work, judging from our own experience. I would add, however, that I think you will find a marked difference in different colonies. While some will adhere to the hive in its new location, without very much trouble, the bees from another colony will persist in going back just as many times as you restore them to their combs and queen.

THE FIRM OF JANE MEEK & BROTHER.

A Serial Story in Ten Chapters.

BY REV. W. D. RALSTON.

CHAPTER IX.

THE DILIGENT REWARDED.

WHEN old winter began his icy reign, the bees were placed in the cellar. As they were increasing in numbers, it each year became more and more of a task to place them there. This fall Tommy constructed a hand-barrow on which he and Jane placed the hives and carried them into the cellar. During that winter, nothing occurred worthy of notice. Jane and Tommy were in school; and their studies, with the sports and excitements of the playground, almost drove all idea of bee-keeping out of their minds for the time.

Mr. Shaw, the grocer, who had purchased their honey, placed it in a position to be seen by all his customers; and if any inquired about it he was careful to explain that he had purchased it from a little boy and girl who had raised it. Much inquiry was made about how it was secured in such frames, and all so nicely filled. He could only refer them to Mr. Meek for this information. Several persons met Mr. Meek in the town, and asked questions about bee-keeping, and the kind of hives to use; while others came out to his house to see his hives and fixtures. If the children were at school, Mr. Meek took pleasure in showing them these, and explaining their uses; in fact, it usually amounted to quite a lesson in bee culture.

Good Mr. Brown was frequently a caller at Mr. Meek's, for they were warm friends. Frequently he asked the children how they liked keeping bees, or how they were succeeding, and heard their report. One day he said to Mr. Meek, "I am almost sorry I gave that hive to the children, for you are wasting so much money on bee-fixtures. I have kept bees for fifteen years, and I assure you it does not pay."

Mr. Meek began to discourse on the improvements which have been made in bee culture, when Mr. Brown shook his head, saying, "I want to hear none of your new-fangled notions. These so-called improvements are the inventions of *gouges* who are after people's money. I am truly sorry to see you waste your money on such fixtures."

One day in the fall, soon after the children had sold their honey, he came in, and, with a queer expression on his face, asked, "Did your children sell Mr. Shaw that pile of honey he has in his store?"

"Yes," replied Mr. Meek; "and besides, they gave us over seventy pounds to use here at home."

"Well, now," said Mr. Brown, "that does beat all! Last spring I stuck an empty fish-kit on one of my hives, and the bees filled it with nice honey. As I had enough without it, I took it to Mr. Shaw's store. He refused to buy it—would not even look at it, and showed me what a pile of honey he had on hand, and said he got it all from your children. He said he would never sell any more honey, unless in little boxes like those in which your children had it. I looked at some, and found them the nicest combs of honey I ever saw, and could be handled so nicely without waste. I took my honey to another store, and could not sell it there. I then took it to another, where I was offered nine cents a pound in trade, which I took, and even they did not buy it very willingly. Now, you know I always have opposed you when you wanted to present new ideas about bee-keeping; but what I saw in the store, of the result of improvements, makes me think otherwise. If you have time to spare, I do not mind to take a look at some of your fixtures, and see what you have to say about them."

As they did so, Mr. Brown would rub his hands, and exclaim, "Well, well, well! that does beat all! I never thought bees were such curious creatures, or that they could be worked with in such a way. I wish I had learned about them when I was young. I guess I shan't begin now. But I tell you what I will do. My youngest children have caught this bee-fever from yours, and talk so much about bees that I will give them mine on certain conditions, and let them make their best of them. I hope they may succeed as well as yours have done."

At length spring came; but the weather was so unsettled that the bees in the cellar were not disturbed until late. One day, all things indicating pleasant weather, the children carried their hand-barrow to the cellar, and, closing the entrance of a hive, placed it on the barrow and carried it out to the yard. After placing it on its summer stand and opening the entrance, they were much surprised at seeing not a single bee making its appearance. On opening the hive they found not a living bee in it. They were terror-stricken. What if all their colonies were dead? They hastened to bring out another; but as soon as its entrance was opened the bees poured forth. It was so with the other seven. Mr. Meek examined the dead colony, and said the cause of its death was the loss of the queen and their failure to raise another. They had an abundance of nicely sealed honey. They took these combs and exchanged them for empty combs in light hives. They prepared two colonies for extracted honey, and six for comb. The extra combs obtained from the colony that died were divided between the two upper stories intended for extracting. To preserve these combs from the moth, they placed on these upper stories containing them, in the time of fruit-blossoms. They had sections also ready to put on the hives as soon as the white clover opened. When they put these on they also looked into the upper stories of the extracting-hives, and were gratified at seeing them full of bees, and were satisfied that work in those upper stories had already been begun. Tommy, by the advice of his father, prepared two upper stories, similar to the others; and when those were well filled, Mr. Meek helped to raise them and place on the empty ones, placing the full ones on top. As the frames in these empty ones were provided with wide strips of foundation, the bees were not long in drawing these out and completely filling the frames with comb. When the upper sets of frames were completely capped they were taken out, carried into the house, uncapped, and extracted. Mr. Meek then raised the next story while the children slipped under it the other story filled with the freshly extracted combs.

The two hives from which they extracted were early strong in bees; and as they did not swarm, the yield from them was 368 lbs. They made all needful preparation, and also kept all as busy as they could. The yield from white clover was not so good as on the previous year; but they had a good yield from fall flowers, which made the year a better one for bee-keepers than the preceding one. Two of the colonies were so busy gathering honey they did not swarm at all. Two others swarmed only once, and one swarm went to the woods. So at the close of the season they had only five of an increase, making their colonies number thirteen.

One day, near the close of the yield from white clover, they, with the help of their father, removed the sections from the hives prepared for comb honey, and, taking out the two outside combs, extracted the honey from them and returned them, that the bees might fill them with honey from fall flowers, which is usually of an inferior quality, and not so ready sale, but does for winter stores. From these they obtained enough to make their crop of extracted honey weigh 500 lbs. Extracting those outside combs doubtless made the yield of comb honey less than it would have been. Their yield of comb honey was only 550 lbs.

Although nothing has been said about stings since Tommy received his first one, you are not to suppose they worked all this time and escaped without receiving another. They had received so many that a sting or two were generally expected when they had much work to do in the apiary. In fact, a dread of being stung often kept them from doing needed work, until their father urged them to it. Tommy took many a dance in consequence of some cross bee touching him on a tender spot; and Jane had often run from the apiary with a bee in her bonnet, calling upon her mother to help remove it. One evening she received a sting on her nose, between the eyes. The next morning, when her mother entered her room to call her, she could hardly believe that the girl she found in the bed was her own little Jane. Both eyes were closed by the swelling, and she looked like an entirely different person. Her appearance at the breakfast-table was greeted with a hearty laugh from both Tommy and her father; but now the stings had ceased to produce swelling as formerly.

The day they took out and extracted the outside combs from the lower stories was a rather unfortunate day for Tommy. The bees seemed very cross, and to have a spite at him; but he received sting after sting. At dinner he said, "I wish bees had no stings!"

His father replied, "Bees have very precious stores to guard, and require arms to guard and protect them. They have an army of lancers who stand guard over these stores. If let alone, bees are harmless; but when we try to rob them of their stores, this army of lancers charge on us. If they did not thus guard their stores, all animals that have a sweet tooth, and men and boys, would feed upon the products of their labor, and they could have no heart to work and gather stores. It is the fact that bees have stings, and use them, which makes it pay to keep bees. If they had no sting, so many would keep them that honey would bring almost nothing in the market. As it is, skill is required to handle bees and not be injured by their stings. Few acquire this skill. Patience is also required, and few attain that patience. Hence bee-keeping becomes a business, and can be engaged in by the skillful and patient as a means of livelihood.

Concluded next month.

APICULTURE A SUITABLE AVOCATION FOR WOMAN.

A RECREATION AND RELIEF FROM HER DAILY ROUTINE.

ALL persons are not born bee-keepers, or even made bee-keepers by years of experience, and it would be but folly to expect that *all* would be successful in that branch of industry. And, indeed, there is often more profit in bee-keeping as a recreation than in all the many returns that are realized, although there is sometimes a consideration in *that* respect.

When the weary rounds of business have become so monotonous that the heart at times sickens at it all, it is then a real relief to turn away from all these things and watch that "band of united workers who never strike" nor complain, moving so systematically along in their ceaseless toil. There is a practical lesson to be learned in watching these uncomplaining little workers. We who so often grow weary of our toil; who so often complain that our labor brings in no returns, can learn some valuable hints from the busy bee that expects no returns save a bare subsistence.

For the overworked, and those whose occupation consists of one changeless round of drudgery, we can not too earnestly recommend this employment. It has been argued by some, that woman is not physically fitted for this business; and by others, that it is unladylike. To such weakness as would prompt the latter thought we have no reply—nothing but a contemptuous pity! That woman is not strong enough for the more laborious part of bee-keeping as well as for many other things which come within the routine of domestic life, is only too true; but is there not for women, and especially on the farm, other back-breaking weights that have far less sweetness in them than honey-boxes? Most farmers' wives have no Irish or negro help to lift their wash-tubs, churn the butter, or do the various other hard jobs that are daily to be encountered.

It has been estimated that a large per cent of the insane entombed in the asylums are *farmers' wives*. Why is this? Simply because there is too much sameness—too little recreation in their lives of toil. Their work brings no remuneration; and woman, as well as man, is only human, and would like some little individual income or possession; and so, sooner or later, the oft-recurring duties become tasks, and life is, at length, reduced to the sphere of slavery.

This recreation among the bees is not at all needed where women are musicians, and can while away an hour or so each day on the latest sheets of music at the piano; or where she is educated to sketch, or paint on silk or velvet—painting the bee or butterfly on some household ornament; but really half the women on farms would feel guilty of some misdemeanor if seen at such employment—so thoroughly have they been taught to know nothing but *real work!*

Then, for mercy's sake, do not try to set up a "scarecrow" over bee-keeping, silk culture, or any other occupation that will be at all remunerative, and tend to lead the mind away from these unchanging household duties—duties that are all right and proper that every women should perform, but nevertheless need to be at intervals sweetened by change. There is nothing dishonorable in any honest employment. It will do to tolerate such sentiments under a monarchical form of government, where an idiot may be born an aristocrat; but we have only self-made aristocracy, and the canal-boy or rail-maker can reach the highest seat under our government, as well as the great. But we would advocate opening up all avenues to woman as well as to man; that is, all that are retired and not calculated to degrade her, which, if she has a love for it, we feel that bee-keeping could never do. Unless there is a real fancy for this business it is a mistaken calling; for bee-keeping, like every thing else, must be entered into with the whole heart to prove a success. But from practical experience, and not from theory, we can say that the sixty colonies which claim our daily individual attention are a real recreation. It leads the mind away from the humdrum cares of life into the study of nature, where its broad fields are spread out before us, rising to the sublimity of its heights as far as the weak human intellect can go as we watch the all-unconscious bee go forth in its ceaseless toil.

If all laborious work is to be taken away from woman because it is unladylike, let it then commence where the general health is most affected, and the mind least diverted, that the sphere of domestic life in general may be more bright and cheerful. A WOMAN.

Greenville, Ill.

PATENT DRONE-BROOD EXTRACTOR.

CHICKEN SHORTCAKE.

WHENEVER we had a lot of drones we used to destroy them with puffball, as some call it, which can be put in the smoker, the drones meantime having been set in a tight box. A few puffs will make them senseless, when they can be taken out and given to the chickens, which will consume all of them before they can fly again. The reason why we did not sulphur them is, that the chickens don't seem to like them so well, nor do I think that they are so beneficial to them when dead.

When I was a boy, and had but a few hives, I would often kill most of the drones of a hive when I knew they were driven down to the bottom-board, which the bees do when pasture gets scarce, or after a young queen is mated. I lifted the hive and put them through the above process. But the best chicken-feed consists of drone-brood from about 15 days old to mature; and what excellent drone-brood extractors chickens are! I found out accidentally, several years ago, when I had my bees several miles from the city, as usual, when late one day I had transferred a few box hives. By packing up, in a rush for the home train, I had left a large piece of well-capped drone-comb on the ground, which I found, when I came back the next day; but to my surprise I found the brood on the upper side was all taken carefully out. As I had noticed chickens around there, it struck me that nothing else could have likely taken it. I turned the comb up the other side, and soon had the chicks to extract it. As we had a lot of chickens this year, and plenty of box hives to transfer, I had plenty of what we call now "chicken shortcake," for which all the drone-brood was used. As I ran short of hives for want of time, I inverted all my remaining box hives, cut out all the drone-comb, before it could hatch, with my hoe shaped instrument.

Now, friend Root, I know that you have not much sympathy with patents or patent men; but as it seems to be fashionable to call every thing an invention, I leave it with you to decide who is the one entitled to the patent—the chicken or myself, for extracting drone-brood.

C. H. LUTTGENS.

Hammonton, N. J., July, 1886.

Friend L., no doubt your suggestion is a valuable one. I presume you use chickens of just the right age, for I could imagine that large fowls might tear the combs badly. I should think the food would be very stimulating to the chickens; but is it not rather expensive? Would it not be better to prevent the rearing of drone-brood by removing all the drone-comb?

KITCHEN CONVENIENCES.

FRIEND TERRY GIVES US SOME USEFUL SUGGESTIONS IN THE MATTER.

FRIEND ROOT:—Now about those improvements indoors. We will take the kitchen first. Here the farmer's wife and daughters spend a large part of their time. The interests of humanity demand that the air in this room be at all times as pure as possible. The farmer who works out in the open air is healthy and robust, as a rule. Now, the kitchen should be as near an approach to open air as it conveniently can be. A tent would be about perfection, for summer; something to keep the rain and sun off during the heat of the day, while allowing a perfectly free circulation of air at all times. Practically, about the best we can do is to have the kitchen in a wing by itself, with outside doors and windows on at least two sides. Then over these doors and windows on each side I would build a large porch. This allows almost as free a circulation of air during the summer as a tent would, and the women-folks have one chance at least for as good robust health as the men have. The windows should have pulleys and weights so the upper sash can be let down or the under one raised very easily for ventilation during cold weather, no matter if it takes a little more fuel. What is a little wood or coal by the side of good health? A physician in the Northwest tells me that, to save coal, which is quite valuable there, many make their houses very tight, and never ventilate any more than they can help, and the result is often a breaking out of typhoid fever, from breathing such filthy, impure air.

It has often amused me to see people who were extremely neat and clean in every other particular so extremely filthy in the matter of ventilation. It is a serious matter; but it is so inconsistent to work so hard to have those pans and dishes and clothes so perfectly free from a trace of dirt or filth while one is breathing the filthiest kind of air. Every breath from our lungs is defiling the air, as are also the emanations from the pots and kettles. The neat housekeeper is constantly washing her hands, when they become soiled in the least; why not wash the air, when it becomes almost sickening from the impurities in it? It is far more important that you should. Dirty hands would only offend the taste, while dirty air is seriously injurious to health. Let the outdoor worker, when he comes into his wife's kitchen, and can "scarcely breathe," fix it immediately so that she may have as pure air as he does to work in, and get his reward in her better health and longer life. Certainly the poorest can afford so cheap a luxury.

Of course, every man will have a pump in the kitchen, and dry wood or coal in the woodshed, where it can be got at handily. I do not need to speak of such matters. Also he will see that there are screens in all the doors and windows, so the good wife may not be annoyed by flies while she is busy with her work. These are almost as cheap as pure air now.

Then if he is like the writer he will have a slop-barrel on wheels standing by the west porch (in the shade) in the morning, and by the east one in the afternoon, so the ladies can dispose of the waste water with the least possible trouble, and with no danger to the purity of their surroundings.

One more point, not to be overlooked: The kitchen is a hot place when the thermometer is in the nineties, and a large cook-stove is adding to the heat. Even if the air is pure it is a terrible place to work, day after day, through the heat of summer. Now, we have it in our power to make kitchen life much more pleasant during the heated term. With a good oil-stove all the work can be done just as well, and one would hardly notice that there is any fire in the room. Our folks are right in the midst of washing this morning. I have just been down to see how the thermometer stood. On the east porch it was 92°; on the west one, 84°; in the kitchen, 84°; and in the main part of the house, 79°. Two oil-stoves were burning under a boiler of clothes. I can easily imagine how hot it would have been in the kitchen if the fire had been in the cook-stove. As it was, the temperature was the same that it was on a cool porch on the shady side of the house, and but 5° warmer than the coolest place in the body of the house. Thanks to the oil-stove. We have a range of three oil-stoves, and you may walk through the kitchen in the hottest day of summer, when the oven is full of baking bread, and my wife is ironing, and cooking dinner—all the stoves burning—and you will hardly notice any difference in temperature between the kitchen and parlor. There are oil-stoves made that are safer than any cook-stove; and the oil bought by the barrel will cost no more than wood at the price it is usually sold at in the village market. That is, *here*, at least, I can take wood to town and sell it for enough to pay for oil that would do the same amount of cooking.

A niece of the writer has no cook-stove in the house. The kitchen is warmed in winter by a furnace, the same as the rest of the house. But I would not advise this. Use the cook-stove during cold weather, and even cool mornings and days in summer, lighting the oil-stove whenever the cook-stove makes it uncomfortably warm. This will be the best economy, and the most healthy practice. Often on a cool morning, when you wouldn't have any fire in the furnace or heating stove, a little fire in the cook-stove would be pleasant, particularly to the older people, and conducive to health by driving out dampness. For ironing, the oil-stove is simply perfect. At first my wife thought that she couldn't make a success of baking bread; but I got her some new tins of just the right size, and experimented a little for her, and now she will bake an oven full of bread in 40 minutes as nicely as it can be done in any stove oven, at a cost for fuel of about half a cent. Women, like us men, are sometimes a little old-fogyish. The first time my wife undertook to get dinner on the oil-stove the potatoes would not get done on time. Dinner was an hour late. That upset her, for she can not bear to be behindhand. She made some pretty strong remarks about oil-stoves in general, and hers in particular, and was more than ever in love with the good old Stewart cook-stove that she had worked over for twenty years. I got dinner next day, or, at least, stewed the potatoes. First the bright new tin steamer was smoked on the bottom, as it always should be, and then just water enough to make steam—about a quart—was put in. Being a little nervous, we started the thing 20 minutes sooner than the directions said was necessary, and had dinner ready 20 minutes before the time! The wife gave up with good grace, and has since gone back on the old Stewart, even for steaming potatoes. A good oil-range will cost about $25, with all the fixings. I was once looking at a friend's nice stone walks, and remarked, "They must have cost you a good deal."

"Yes," he says, "there is less money in the bank, but a mighty sight more comfort around home."

The same may be said of the oil stove.

Hudson, O., Aug., 1836. T. B. TERRY.

Friend Terry, I most emphatically agree with almost every point you make; but I notice you speak of *coal-oil* stoves, and say nothing about gasoline. I presume your objection to gasoline, judging from what you say on page 535, is the danger; but are not stoves for gasoline now made so that the chances of danger are reduced to a minimum? We have tried coal-oil stoves, and gasoline too; but we find the gasoline rather the more convenient; but we should like to have your ideas on the subject while we are discussing convenient kitchens.—In regard to pure air, I am getting of late so that it is very hard for me to remain in any room very long unless the air is pretty nearly as pure as I find it outdoors.

SEVERAL MATTERS FROM FRIEND HEDDON.

QUEEN-EXCLUDING HONEY-BOARDS.

YES, they are a grand success. I think that Dr. Tinker's article in last issue, supplemented by your copy of my own from the *C. B. J.*, must shed some light upon the whole honey-board question. I think the doctor was first to publish the device of the unity of the metal strips with the wooden slats, by letting the metal into side-grooves; and he is entirely correct in saying that to him who first published it to the world, belongs the credit. We gladly accord it to the doctor, though we three, who were original in the same thought, had none of us ever seen it in any honey-board before.

MRS. CHADDOCK'S HONEY.

I am sorry to read the low prices Mrs. C. tells us she is selling her honey for. I think such low prices for comb honey are entirely unnecessary, and would, if long compelled, drive us all out of the business. On page 631 you quote Mr. Doolittle as "answering the wail of a few;" but take him as authority as to the cost of producing honey, and where is Mrs. Chaddock's bee culture going to end? She is selling at a price below the cost of production, according to Mr. Doolittle, and I think his figures are about right.

SHALL WE EXTRACT DARK HONEY?

I say, "Yes." I notice your foot-notes to Mr. Pond's article; but I must say that I think you are in error. Give me all light honey in the comb, and all dark extracted, for most profit. I do not speak theoretically, nor from a local experience; but after jobbing and wholesaling many tons in nearly every Eastern, Middle, and Western State in the Union.

HIS 25,000 LBS. OF HONEY, AND HOW TO DISPOSE OF IT.

Since the great loss of three-fourths of my bees during the severe winter of 1884-'85, I have been compelled to raise extracted honey mostly, and this year we have 25,000 lbs. of as fine thick clover and basswood honey as I ever saw. I am having no trouble in getting 8 cts. per lb. for it, at our depot, in 50 and 100 lb. lots, packages thrown in. Perhaps you will remember my articles on the taking and caring for extracted honey, on pages 625 and 659 of GLEANINGS for 1885. You will recollect what I said about the results in disposing of our crop, if we would only take the pains to produce an article of extracted honey that is in every respect as nice and smooth as the best comb honey. Well, I find the results as there predicted; for my customers will not leave me, even if they can buy extracted honey, from the same blossoms, at 2 cts. less per pound. You recollect the raspberry honey you sent me, at a low price. Well, friend Root, it is not eatable, simply because it was either taken before it was ripe, or else allowed to degenerate after being extracted. I see a new and grander future for extracted honey, when our producers will supply a choice article; but I sample scarcely any, as I find it on the markets, that is good for table sauce. I am compelled to admit, that most that I have produced has been of inferior quality; but for the past three years I have found the better and far more profitable way. I believe the time is near at hand when I can job out 50,000 lbs. per year, at prices that will pay for producing.

"OUR NEIGHBORS."

I am sorry if you have made haste to print a lot of circulars after the copy of Mr. Cameron's paragraphs, as found on page 619. We know that these statements come from a man of good heart,—we believe from a splendid man; but we think he has made the common error of misjudging the class he has written them for. If all the readers were living and thinking on this elevated plane, his statements to them would be of much service to all; but such is not true, I am sorry to say, and I believe that such a circular would do more harm than good.

This article is now long enough; but if you choose I will point out to you the whys and wherefores, and suggest such subtractions, additions, and alterations, as I think would make it a circular of value. JAMES HEDDON.

Dowagiac, Mich., Aug., 1886.

Friend H., I think many would disagree with you in regard to the raspberry honey. The flavor is peculiar, yet I do not think it unpleasant. I should not, however, call it equal to the sample kegs of honey you sent us.—In regard to our neighbors, I am sure the circular referred to will do good among many classes. We should, however, be very glad to hear your corrections, alterations, and suggestions in regard to said circular.

"OUR OWN APIARY."

A GOOD REPORT FROM THE HEDDON HIVE; WORKING FOR COMB HONEY.

IN Aug. 1st No., page 605, Bro. Heddon says Bro. Hutchinson seems to be carrying this problem all alone, and that he receives many adverse reports. In all reports I have seen of tests of Bro. Hutchinson's plan of securing worker-comb without foundation, the parties have violated one or more of the principles as laid down by him. One fails to put on the surplus-case at time of hiving swarm; another put in a frame of brood. To succeed in securing all worker-comb with this plan you *must be sure* to put on the surplus-arrangement *at time of hiving*, and not next day nor next week, as some report doing, as in that case they will *build only drone-comb*, if a prime swarm, and strong enough to be worth any thing for surplus honey.

I am using the new Heddon hive this season, and have succeeded in getting as much surplus honey without foundation in the brood-chamber as with it, and the brood-frames are full of nice worker-comb which cost nothing. I use one section of the hive with foundation starters not over one-half to one inch wide, in the brood-frames, with queen-excluding honey-board above, and put on a case holding sections before I hive the swarm; part of the sections were full of foundation, and part with only starters. Others I arranged the same, except I filled the brood-frames full of Dadant foundation, and the colonies with empty frames have made as much surplus as those with full frames; and in neither case did they build drone-comb in frames or sections. In one experiment I used hybrids with full and with empty frames; in the other, Italians. The swarms hived on full frames in both cases were stronger than those on empty frames, and with this seeming advantage failed to come out ahead.

QUEENS AND SWARMING.

I am convinced, from experiments with several colonies this season, that the young queens do not hatch until a very short time before a second swarm leaves, and that the worker-bees control all swarming themselves. Several years ago I saw queens fly in less than one minute after coming out of the cell; and several times, on cutting out queen-cells, I have found no queen hatched, even when the queens had been calling one or two days, but with the cap of cell cut nearly off; and as soon as they were taken out of the hive the young queen would come out. I also had a colony of blacks in which the young queen was calling before they swarmed; and by taking the frame containing the young queen I made another colony which has never swarmed, and this is the fourth season since then. This season I have tested it by waiting two days after I heard the queens calling, and in no case did I find a queen hatched, but the cap cut loose on one cell; and as soon as the frame was taken out of the hive the queen hatched; and by cutting out all other cells there were no second swarms. If the bees decide to swarm after the prime swarm, they keep the first queen from hatching when she wishes to; and then she begins to call, and the other queens in cells old enough answer her; and when they are about ready to leave they allow one queen to hatch; or if they intend to send out only one second swarm, they let all queens old enough hatch and go with the swarm. If they decide not to send out a second swarm they allow the oldest cell to hatch as soon as the queen is ready to come out, and then destroy the other cells, and you hear no calling of queens. 9—JOHN C. GILLILAND, 15—24.

Bloomfield, Ind., Aug., 1886.

SWEET CLOVER, OR MELILOT.

FRIEND GREEN GIVES US SOME NEW AND IMPORTANT SUGGESTIONS IN REGARD TO THE PLANT AND ITS HABITS.

THERE is a great deal of sweet clover in this locality, growing along the river-banks and other waste places, as well as along the roads, which in some places are lined with it for miles. I find that most persons are apt to regard it as a nuisance along the roadside, and many land-owners wage war on it with more or less persistency and success. Some of the objections which they make to it are well founded, while others are unfounded or unimportant.

The principal reason why it is objected to, I think, is the fear that it may prove a noxious weed. It is a strong, rapid grower, readily becoming established, usually holding its own tenaciously when once it gets a start, killing out other plants, and spreading from year to year. These are the recognized qualities of the worst weeds; and the farmer who sees it march along the highway and settle down in front of his place, as though it had come to stay, is apt to be alarmed at the thought that some day it may take a notion to invade his fields in just that way. His fears are groundless, though. Its seed will not start in a close sod; cultivation readily kills it; and even after it has taken complete possession of the soil, close mowing, so as to prevent any seed from maturing for two successive seasons, will eradicate it completely.

I have ridden for miles along a road where all the space between the fences, except a narrow wagon-track, was thickly covered with sweet clover, yet not a single plant was to be seen inside the fields. I have occasionally seen sweet clover growing inside the fence along the roadside; but it is a suggestive fact, that it is almost always the old tumble-down fence that lets the sweet clover through, while a good fence keeps it from the well-tilled fields beyond, as completely as it repels stray stock. There is a moral here, if you go deep enough.

The most reasonable objection to sweet clover along the country road lies in the fact that its tall rank growth often makes a close hedge four or five feet high along each side of the narrow wagon-track, thus cutting off all breeze from the horses. This close hedge, too, sometimes makes it difficult to turn out far enough to allow a team to pass. In this locality farmers frequently herd their cattle along the roadside when pasture is short, and these complain that sweet clover occupies the land to the exclusion of grass. Cattle will not eat it except when it is young and tender. Other objections are sometimes heard, most of which will apply quite as well to any other weed.

Now, what can we say in favor of sweet clover to the man who cares nothing about its value to the bee-keeper as a honey-producing plant? I can only say that it often takes the place of less desirable plants, and that its modest blossoms with their grateful perfume combine to render the highway beautiful and fragrant. Can we say any thing more practical? I hope some one can give us reasons more convincing to the average farmer, why this valuable honey-plant should be allowed to grow on the roadside.

Many who object to the rapid spread of melilot on the highway, accuse the bee-keeper of planting it, when they themselves not only cultivate the ground but sow its seed. Sweet clover, unaided, can do little to extend itself. Its seed is too heavy to be carried far by the wind, and it is not provided with any means of attaching itself to passing objects. The most efficient agent in distributing its seed is the man who leaves the ordinary track for the roadside when the roads are muddy in the spring. In this way the surface of the ground is broken up and prepared for the seed, while the wheels of his wagon and the feet of his horses, sinking into the ground where seed fell the autumn before, pick up portions of the soil filled with the seed and carry it along for rods and sometimes for miles, and there drop them to form a new nucleus of growth. Sweet clover is apt to spring up wherever any grading of roads is done; and the man who plows the roadside for the purpose of scouring his plows, though an enemy to humanity in general, is a friend to the bee-keeper in a sweet-clover district.

While under favorable circumstances the seed will grow and do well if sown at any time of the year, it will be much more apt to grow on uncultivated ground if sown in the fall, so the snows and rains of winter and spring may beat it into the ground.

You are probably right as to the cause of the sooty color of the honey sent you by friend Muth. The sweet-clover honey gathered here is nearly if not quite as light colored as that from white clover, while the flavor is, in my opinion, superior. When the honey is unmixed it requires no expert to tell that it was gathered from sweet clover, especially if freshly gathered. In extracting newly gathered sweet-clover honey, the current of air coming up out of the extractor is laden with a perfume as distinct and unmistakable as that experienced by holding a bunch of the blossoms to the nose. We had promise of a good yield from sweet clover, and indeed it started out well; but the long drought has checked its yield so that what honey we get is considerably mixed with that from other sources. If it were not for this I would send you a sample of the honey, which I think would compare favorably with any you have ever seen or tasted.

Dayton, Ill., Aug. 10, 1886. J. A. GREEN.

Thanks for the additional facts you have given us in this matter, friend Green. I believe you are right in regard to its propagation and extension along the roadsides, by its being carried along by vehicles in the way you suggest. I am glad to have my opinion corroborated in regard to the quality of the honey. I should like to know if anybody has been successful in raising the plant by the acre. It seems from the above, and from what others have written in regard to it, that a different treatment will be necessary from that given to ordinary cultivated plants.

A VISIT TO OLIVER FOSTER'S APIARY.

FRIEND BRUBAKER GIVES US A PEN SKETCH OF IT.

AFTER two months of constant work in the apiary I was thoroughly tired. The dry weather put a sudden stop to the honey-flow. After basswood bloom, and while the bees were taking a little rest, I concluded to take a little play. I had written friend Foster a line, stating I was going to the east part of the State; and as I would pass within a few miles of his apiary, if agreeable I should like to stop off and visit him and see his methods, etc. He not only informed me, by letter, that he would be pleased to have me call, but also said he would meet me at the depot.

On the 29th of July I took the train at Maxwell, and was soon speeding eastwardly over the fertile prairies of our beautiful State. The effects of our all-summer's drought were visible on all sides. The pastures, instead of wearing a mantle of green, as is usual for this season of year, were all dried, and "brown and seer." The dry beds of brooks and streams, the wilted corn, the dried-up appearance of gardens, and the many fires all along the 130 miles I traveled, which had originated from sparks from the engines igniting the dry grass, all plainly told of the serious effects of the protracted drought.

Reaching Mt. Vernon at 10 P. M. I took lodging at the hotel, instead of going to friend Foster's. After a sound sleep I was up at five, ready for a walk; but the little city was all silent in slumber at this early hour. Naught but the sound of the melancholy katydid, and a few low notes of birds were heard to break the silence. A few minutes' walk brought me to a point on the shady street where a pleasant landscape was presented to the sight. Nestling down in a small valley in the midst of a shady clump of trees, stood a cosy little house. To the south, near by, stood a large number of hives, arranged in blocks and alleys. Close by were the work-shop and honey-house, all neatly painted. I recognized this at once as being "the place."

On entering the apiary the first object that especially attracted my attention was a little girl-baby, about two years old, standing near the corner of the house, with little curls reaching down over her little forehead, calling for papa. I felt somewhat disappointed when the timid little darling refused to shake hands or enter into any conversation. It was only a few seconds after when I introduced myself to the "boss of the ranch," whom I found in the shop, and in a very short time we were talking bees and honey and fixtures as if we had always been acquainted. Mr. Foster is a young man, 29, full of vim, and a lover of his chosen occupation; and, judging from the number and character of his apiarian fixtures that he has invented, it is easily seen that he is possessed of more than ordinary inventive genius. He has in his home apiary 225 colonies; and located about 5 miles north are 100 more —in all, about 325. Up to date he had extracted 10,000 lbs., and taken 4000 lbs. of comb honey; but, like some more of us, he lost considerable honey by not having every thing in readiness quite early enough. He has also sold and shipped 126 nuclei, at an average of $3.43, besides quite a good number of queens by mail. After figuring up his profits mentally for a few moments, I was almost ready to believe what the landlord at the hotel had told me the evening before, when, on inquiry as to whether he knew a bee-keeper by the name of Foster, in the town, "Yes," said he; "I knew him when he started in the business ten years ago, a poor boy, and now he is making more clear money, I think, than any other man in town."

Whether this is strictly a fact or not, a glance at his premises tells of prosperity; and while he works hard to make it win, I was led to think, while in his little home, "No wonder his business is prospering." When, at the beginning of the day's labor, though a very busy time, the Bible, that best of books, was taken from the stand, and from its holy pages a chapter was read, and an humble invocation asked of the Dispenser of all blessings. How could it well be otherwise than that, with hard work and the blessings of Heaven, a man should prosper? I think I never saw so many colonies together, where all were so uniformly a fine type of Italians. I left, much benefited by my visit, and *almost* missed my train in the evening for having been absorbed in conversation with friend F.

I must quit now, short off. I hope no one will think hard for my giving my friend such a friendly notice.

So far as I have been able to learn, honey is selling at about 10 cents for extracted, and 12½ to 15 cents for fine pound-section honey.

Maxwell, Iowa, Aug. 2, 1886. D. E. BRUBAKER.

Many thanks, friend B. We have enjoyed every word of your account of your visit, from the curly-headed little girl to the time you almost missed the train; and especially that part of your talk where you mention friend Foster's taking down the Bible at the beginning of each day's work.

FOUL BROOD, AND ITS MANAGEMENT.

DIRECTIONS FROM PROF. McLAIN, OF THE U. S. APICULTURAL STATION.

MR. E. R. ROOT:—Your father told me last week that you were having some trouble with foul brood. I told him that I would send a prescription for the cure of foul brood, and also a prescription for use as a preventive.

Take of soft water, 3 pints; of dairy salt, one pint. Use an earthen vessel. Raise the temperature to 80° F. Do not exceed 90°. Stir till the salt is thoroughly dissolved. Now add one pint of warm soft water in which has been thoroughly dissolved four tablespoonfuls of bicarbonate of soda (use the crystal). Stir thoroughly. Add to this mixture sufficient sugar or honey to sweeten it, but not enough to perceptibly thicken it. Now add ¼ oz. salicylic acid. Merritt & Co., of Cincinnati, make a pure salicylic acid from the oil of wintergreen (Konk's solution of salicylic acid No. 1). Mix thoroughly. Let this mixture stand for two hours, when it becomes settled and clear.

Treatment.—Shake the bees from the combs, and extract as clean as possible. Now thoroughly atomize the combs, using the mixture and a large atomizer. The tinsmith can make a good one for 25 cents. Return the frames to the colony.

If there is no honey to be obtained from the fields, feed honey or syrup to which has been added 3 tablespoonfuls of the mixture to each quart of honey or syrup. Stir well. The honey just extracted may be used without injury to the bees, if the mixture is added; but no more should be furnished than is consumed. Atomize the colony two or three times more, simply setting the frames apart so as to direct the spray well over the combs and bees—not brushing off the bees; three or four days should intervene between the times of treatment. The last may be given on top without removing a frame.

As a preventive, apply on top of the frames, or in any way by which the bees may get it. Also burn old dry bones to an ash, and pulverize. Mix up a gallon to each 50 colonies in the apiary, of the above mixture, adding enough sugar or honey to make it very sweet (say two or three times as much honey or sugar as would be a proper quantity for use in the atomizer). Stir in a full half-pint of the powdered bone ash. Place this gallon of mixture in, say, four shallow vessels—perhaps bread-pan feeders with floats on top—and stand these four in different parts of the apiary. You will be surprised at the rapidity with which the depleted colonies will recuperate and grow strong again.

If you fear that the exposure of sweets in the apiary will induce robbing, the mixture can safely be fed the customary way on top of the frames in the hive.

I would recommend that you give the entire apiary one application of the mixture prescribed *for cure*, as this treatment frequently prevents the presence of the disease where it was not before possible to detect it.

The quantity prescribed for use by means of the large atomizer is sufficient to treat 150 colonies. Not reckoning the sugar or honey used, the cost will not be more than 15 cents. I have prescribed this treatment with entire satisfaction and uniform success for the past two years.

I will mention the facts in two or three of the apiaries for which I have prescribed this treatment.

1. Number of colonies in the apiary, 46; number apparently diseased, 13; number actually diseased, 28; disease so far progressed that the stench was very offensive in the yard; bees crawling out of hives to die, by tens of thousands; effect of treatment apparent in one day; a permanent cure in each case.

2. Number of colonies, 60; serious cases, 38; combs black and putrid; a few had already been burned; effect of treatment apparent at once; a permanent cure in each case.

3. Number of colonies, over 150; number of colonies diseased, 60; bees swarming out; stench from hives nauseating; combs black and rotten; brood putrid; whole apiary treated; disease immediately arrested; effect of treatment on affected colonies instantaneous, even on apparently hopeless cases; every colony cured; disease eradicated, leaving no trace behind. Colonies soon all strong, healthy, and prosperous. For the purpose of further experiment, the combs of healthy and diseased colonies were exchanged; combs from diseased colonies being given the healthy colonies, and the combs of healthy colonies placed in the diseased colonies. The treatment was applied to both alike. In every case the disease would immediately disappear, and in many cases the diseased colonies were soon more populous and prosperous than those which had had no disease and had been undisturbed.

This treatment, which is simple, cheap, and easily and rapidly applied, seems to be efficacious in the most virulent forms of foul brood, and seemingly furnishes immunity from the dreaded scourge.

Aurora, Ill., Aug. 6, 1886. N. W. McLain.

P. S.—The remedy for foul brood—the formula for making and applying, which I sent you, effectually eradicates the worst cases in about 12 days, without the cleaning of a hive or melting of a comb. I am glad to hear that you have no need for it in your apiary. The disease described in Gleanings, as being in your apiary, is, I think, not foul brood. If you have any more trouble with it I can tell you what to do. N. W. M.

U. S. Apicultural Station, Aurora, Ill., Aug. 17.

HOW I HIVED A SWARM UNDER DIFFICULTIES.

HOW A BOY OF 63 SUMMERS MANAGES TO CLIMB A TREE AND TAKE DOWN A SWARM.

ON the second of last month, between three and four P. M., while working in the field I was startled by a swarm of bees passing over my head. I immediately followed, but could not keep up with them, on account of the fences and fields of grain. I noticed what direction they took, and returned, discouraged, to my work. About 6 o'clock I took a stroll through a thin piece of woods to a small creek that runs about ¾ of a mile from where I write. I looked up the trees, to see if I could discover any bees, but to no purpose till I came to cross a fence. In doing this I turned to look back, and discovered a large swarm of bees on the outside small limb of a blackwalnut-tree, about 50 feet from the ground. It looked very tempting; but the question came, how to get it. No ladder was long enough, no long-handed saw to be had, nor anybody to lend a helping hand. I got a handsaw, which I tied round my neck, a box with a frame of empty cells and 6 other empty frames. In trying to climb the tree I found it was too large around the body, in order to reach the first branch. I got a rail, crawled up so far that I could just touch the branch; but when I got on it, I found the next branch still further off. Persevering, and not minding a little skinning of my legs, I reached the second branch, when I had comparatively easy work to reach the branch on which the swarm was hanging. I sawed it off; but in falling it stuck fast to a lower branch, the bees meanwhile ascending to a higher branch, which I cut off immediately, as I reached it, to prevent them from clustering on it. They did not go further up, so I descended, cut every branch on which they lodged, as the branches stuck till the whole concern came down with a crash, smashing the cover to the box. I descended as fast as I could, covered the box with an old coat I had taken with me, and began shaking the branches I had cut off, in front of the box. As soon as I had one clear of bees I carried it off, till I had all the bees pretty well on the ground. Then I picked up a little dry wood, made a smoke to hurry up business, as I wanted my supper, for the sun was going down. I managed to reach home shortly after sundown, with my swarm, carrying it before me, and such a heat they gave off! They are blacks, and I don't know where they came from. In six days they filled 10 empty Gallup frames, and are uncommonly docile. I think the whole business was pretty well done for a boy of 63 summers, not having a veil or hat on, nor being stung once.

MELILOT HONEY SMOKY, AND WHY.

The atmosphere of large cities is heavily charged with coal smoke, which spreads for miles around in such small imperceptible particles that one often does not notice it till he passes his hand over a leaf or flower, when it will become colored black, especially when a little damp. Is that not the cause of your melilot honey being smoky, as we do not know any thing about its being smoky around here? F. J. M. OTTO.

Sandusky, O., Aug. 10, 1886.

PREVENTING INCREASE, AGAIN.

MR. HEDDON'S CRITICISM.

ON page 562, Mr. Heddon says: "Referring to page 529, on 'Preventing Increase,' it is quite easy to see why Mr. Robbins failed of success," etc. Ever since reading that, I have been wondering what it is that can be so easily seen. I know better now than I did when I wrote the article referred to why I failed; but I gave no intimation of it there. Is it because I was careless, or did not follow the method properly? or was it because of the swarming mania of my bees? Please do not be afraid to speak out, Mr. Heddon. I might add here, that I have not known a failure of said plan when properly followed this year, although the swarming instinct of my bees seemed about tripled, more or less, but I have been unable to practice it much.

We are too apt to render "snap judgment" concerning these things. I have faith in this method; and because some of us may fail with it, or any other such devices, is no proof that the principle of it is not correct. My mother can take Graham flour, an egg, with some salt, soda, and buttermilk, and make Graham gems that will fairly melt in one's mouth. I might take those same ingredients and follow her directions, and make nothing good but a good failure. Should I conclude that flour, salt, soda, buttermilk, and egg, will not make good gems? Nonsense! You see, it all depends upon how it is done.

While I am on this subject I would say that a great deal depends upon adaptation. Our gifts, habits, and conditions, are so diverse that we can not all do things best the same way, and we must have systems adapted to our ways. My mother can make the best gems, her daughter-in-law the best cake. I certainly do not believe that the Simplicity is the *best* hive, but A. does. It suits him—it does not suit me. Adaptation, usage, conditions, these apply to little things as well as great; and if we would bear this in mind we would not make so many confident assertions in the controversies over methods and systems in apiculture. This is not all, but I shall stop here. You see I have wandered; but I have done so because one thought suggested another.

THAT QUEEN-EXCLUDING HONEY-BOARD.

I am bound to have a queen-excluder of some kind, and I believe that the one illustrated on page 613 is just the thing. I have not been nearly satisfied with any thing of that kind that I have seen yet, except that one. But the board, as Mr. Heddon describes it, has the bee-space all on one side, and is not adapted to the reversible hive. On page 93 of "Success in Bee Culture," he says: "The queen-excluding metal works into these one-half bee-space honey-boards admirably; and for all I can see at present we had better use the metal when we use queen-excluding honey-boards." Is Mr. Heddon or any one else manufacturing such a honey-board?

EMPTY BROOD-NESTS.

I do not intend that friend Hutchinson shall carry this problem quite all alone. If my help is of any advantage he shall have it. I am confident that his system of hiving swarms upon a limited number of frames—empty frames at that—with surplus room above and queen-excluders between, is as near just the thing as we can get. The system fits in every part. Theory and my experience, I take it, both confirm it. True, many of my bees will build drone-comb, however I may work them; but this I attribute to their everlasting irrepressible disposition to swarm. If I can ever control that, I think I shall practice that system altogether. 4—GEO. F. ROBBINS, 57—93.

Mechanicsburg, Ill., Aug., 1886.

Friend R., we stand ready to make any kind of a honey-board anybody wants —part metal, part wood, or all wood or all metal, and we will put a bee-space on one side or both sides; but as the matter now stands we don't dare to make up ahead queen-excluding honey-boards of any kind, for they are changing all the while. I for one should be very glad indeed to find it were possible to settle down on some definite arrangement.

MISLEADING STATEMENTS.

IS IT TRUE, THAT CERTAIN HIVES GIVE A LARGER YIELD OF HONEY THAN OTHER HIVES?

BEFORE me lies a letter from an inventor and supply-dealer in which are these words: "The use of my hives and surplus-cases will give you more honey than you now produce, with one-half the labor;" while further on, in this same letter, these words occur: "My methods will beat yours two to one." In one of the bee-papers I noticed it said, not long ago, that *more than double* the honey could be obtained by using certain inventions; and as I consider such statements fallacious, I desire to explain my position in this matter. While I believe there is little difference regarding the labor required in the manipulation of one hive above another, where a term of years is taken into consideration, still it is not from the labor point that I take exception, but to the greater production of honey. Can it be possible that any man can be so blinded as to think that a bee-hive of his invention can gather or produce honey? Elisha Gallup once said, very truthfully, that, "other things being equal, a colony of bees will build as much comb and produce as much honey in a nail-keg as in any hive, and they will produce as much honey in my nail-keg as in yours." From this we see it is the bees that produce the honey, not the hive; and any of the good hives now in use that meet all the requirements of the bees will give as much honey as any of the new ones for public favor. Wherein one hive is better than another is not in the production of honey, but in its being better adapted to suit the wants of the bee-keeper. Because one man wants 50 pounds of honey in sections on the first of October, with his bees in a starving condition below, while another man wants 25 pounds of this honey in sections, and 25 in the brood-chamber, does not alter the product of the bees in favor of the first, one particle; yet for a big send-off for certain hives the first is claimed to produce double the profit of the second.

Taking the price of sugar and honey into consideration, together with the labor required to get the first into condition to winter equal with the second, there is not a farthing's difference between the two. Several years ago, when honey was higher in proportion than sugar, the cash income might have been in favor of the former; but that would not change the production of honey any. If I am correct in the above, and I believe I am, how can we afford to throw away all of our old hives and fixtures, and invest in these new ones at a higher price, only to reap the same results except in a different form?

As I was almost if not quite the first one to advocate the contraction system for the production of comb honey, I wish to say that all I claim for it is, that it gives me the larger part of the white honey during the height of the season, in the sections, instead of having the same stored in the frames of an uncontracted hive; while later on, when the honey is not quite as white and showy, but equally good for the bees, I get their winter supply in the body of the hive. To accomplish this end I work somewhat as follows: When a colony swarms it generally has the full complement of frames in the body of the hive, which, as a rule, are full of brood. To hive the swarm I simply take their frames of brood out of the hive, with the few bees which adhere to them, and put them in an empty hive on a new stand, when but five frames are put back in the place of the eight or nine taken out, the rest of the space being filled up with dummies. The sections are now put back, and the swarm returned. They are now left for 24 days, at which time young bees are hatching very plentifully, when the dummies are taken out, and frames of empty comb placed in the center of the hive between the brood for a threefold purpose—to keep the bees from swarming again, to give the queen room of a fresh nature in the center of the hive, and for a sufficient supply of honey to winter upon. The brood in the combs carried away soon give a splendid colony, together with a queen given them, so that they in turn give a good yield of honey, and also get in good shape for winter. It will be seen that my aim has been to get all the honey possible in the sections in the height of the honey season, and, later on, both honey and bees in the hive for winter. The above plan may not suit the requirements of any bee-keeper besides myself, and therein is where lies the difference of views regarding hives; but I claim that, aside from this, other things being equal, there is not difference enough between any of the good hives now in use to pay for the cost it would involve to exchange. G. M. DOOLITTLE.

Borodino, N. Y., Aug., 1886.

Friend D., while I emphatically agree with you about misleading statements, if I understand you correctly I can not quite agree in regard to the amount of labor required to manipulate different hives. Quite a number of successful bee-keepers of my acquaintance use hives which, it seems to me, are needlessly complicated; and I have often thought they might just as well get just as much honey with half the labor, if they had their hives and other things arranged more conveniently; and while I do not believe in changing hives very often, I think there are some kinds of hives, even now in use, that it would be money in the owner's pocket to burn up; that is, if he is going to keep bees and produce honey for, say, four or five years to come. I would, however, experiment pretty thoroughly on a few hives of the pattern that seemed to be an improvement, before going to the big expense of transferring and changing over the whole apiary.

EXPERIENCE WITH FOUL BROOD.

FRIEND LONG TELLS US HOW HE MANAGED TO GET RID OF IT.

THE account of trouble at the "Home of the Honey-Bees," in GLEANINGS for Aug. 1, brings to mind the experience I had some years ago with foul brood among my bees. It was in 1878 or '79 that this scourge first appeared. Where it came from, or what its origin was, I do not know, and can hardly say that I have any idea. When I first found dead brood I supposed it had died from cold, starvation, or some other cause, and the disease made good progress in a number of colonies before I was aware of the danger. Colonies containing queens brought from other places were especially affected. I remember a colony containing a queen purchased of J. H. Nellis; one the queen of which came from a breeder in Canada; one having a tested queen from A. I. Root, were all affected. I do not say that these colonies alone were affected; there were, of course, others; but it did seem that the colonies containing Italian queens purchased were especially bad. After becoming convinced that I had foul brood I set about endeavoring to cure it, and put in practice all information I could get from the bee-journals, etc. This was during the season of 1880. I fed salicylic acid, sprayed the bees and combs with an atomizer, cut out and buried the worst parts of the comb, and got the disease much less, but not eradicated. The spring of 1881 I saw but little of the disease; and it being a good honey season, by fall it seemed to have entirely disappeared. I congratulated myself that I was well rid of the scourge. It proved, however, that, by reason of the remarkable flow of honey we had during August, 1881, the disease had been only covered up; for on examining some hives, Feb. 15, 1882, I again discovered foul brood in several hives. It was indeed discouraging, but I did not feel like giving it up, and accordingly went to work more thoroughly than ever.

I now tried D. A. Jones' starvation plan. I took the bees from the combs and put them in the cellar, from 100 to 125 hours; then I gave fdn. in a new hive, thoroughly scalded all ducks, feeders, hives, etc.; melted the combs into wax, and boiled the honey, and by persistent effort was able to succeed in eradicating all traces of the disease. The hives, I did not use for a year or more, but have since made use of them without any damage resulting.

The spring of 1883 I found only several cells in one colony. I watched very carefully, but since that time have not seen a cell of foul brood in any of my colonies. I have never seen any foul brood in any bees in my neighborhood, and have transferred and handled a great many, and consider myself fortunate that I was able to stamp out the disease. The loss was considerable; but the experience gained is of value, for I am satisfied that I know and can detect the disease. E. C. LONG.

Williamsville, Erie Co., N. Y., Aug. 12, 1886.

HAS THE HOME OF THE HONEY BEES REAL FOUL BROOD?

ONE OF CALIFORNIA'S LARGE HONEY-PRODUCERS.

FRIEND ROOT:—I have just received your statement about having foul brood in your apiary, and I feel in duty bound to write you in regard to it, as I had two colonies last year affected precisely as you described. They began to dwindle away, having combs pretty well filled with brood; in a few days I noticed pin-holes beginning to appear, and then I discovered that nearly all the brood was dead. I was alarmed, thinking I had foul brood surely. I kept a close watch, and soon found that there was *no smell* from the combs; and as I had heard of no cases in the neighborhood I concluded to wait and see the result, supposing that, if it were really foul brood, the rest of my colonies would soon contract it; but I had no more of it. The two colonies gradually dwindled and died, the combs of brood dried up so that the cells contained only dust, so I concluded that it was *not* foul brood at all, and gave myself no further anxiety about it. I kept my bees through the winter, and sold them in March last prior to going to California on a short tour of inspection, and I have not heard of a single case either among those I sold or in the neighborhood anywhere. I conclude that it could not have been foul brood, as I did not destroy any hives or combs, and I have great hopes that you are not so badly afflicted as you fear. Could I have seen your article as just published, or one like it, I should have been terribly alarmed. It was only my ignorance that saved me. You know, "Where ignorance is bliss 'tis folly to be wise."

MR. HARBISON'S APIARY; THE MAN WHO HAS 3000 COLONIES.

I regret that I did not know that you had a brother near San Diego, as I would have visited him while there. I spent a week in one of J. S. Harbison's apiaries. It would make you smile to see what he does and how he does it. He uses the "Harbison hive" only—a large box-shaped hive with a door in the rear, made of redwood lumber dressed on the inside only—no paint wasted on any of them, and in the apiary I was in (425), a large percentage of the hives were corked up with rags to prevent robbing. I was there in April. Bees were brooding up, preparatory to swarming. Mr. Harbison told the employees *not* to be careful in manipulating to keep from killing bees. "Mash them in shutting the door, even if a quart were killed in each hive," he said; they would be "all the better for it." This sounded very strangely to eastern ears, as I have always felt it to be cruel as well as wasteful to kill bees at any time, more especially in the spring. Mr. Harbison told me that he takes no bee-papers, uses no comb foundation, no extractor, nor bellows smoker; his smoker is a large sheet-iron box in which he burns chips, bark, or blocks of wood. He uses bits of empty comb for starters stuck on with stiff glue. With all this method he has accumulated a good deal of wealth, so I was informed. He told me that he had 3000 hives with bees in them. He is obliged to keep his apiaries out in the mountain gorges, remote from the fruit-raising interests, as the bees damage the fruit in the drying season.

Mr. Heddon and some one else have said lately that they know of nobody who ships honey in crates as the bees store it. Every one in California who uses the Harbison hive and case ships in precisely that way. J. W. MARGRAVE.

Hiawatha, Kan., Aug. 1, 1886.

Thank you, friend M.; but I am pretty sure we have had at least one form of real foul brood. In our case the smell was very plainly perceptible in every hive that was affected; and as pieces of comb having foul brood have been many times sent us by mail, I recognized the smell at once. Since our last report it has broken out, or commenced to break out, in several colonies in the vicinity of those first affected. The *bees*, however, from those first affected are now rearing healthy brood, and are doing nicely, so we feel confident we shall succeed in killing it out.—I suppose that, in Mr. Harbison's apiary—that is, in his climate, bees are counted of no value; but even if such is the case, it seems sad to think of killing them needlessly.

A FEW KIND WORDS FROM ONE OF THE OTHER SEX.

HOW TO KEEP HONEY FROM CANDYING.

I HAVE been sitting quiet for a long time, listening to the ideas which the brother and sister bee-keepers have advanced, and enjoyed very much reading the talks about bees in GLEANINGS. Not only about ladies as bee-keepers, but many other things about bees, that I found to be very interesting. Especially do I enjoy reading Our Homes. I think those pieces have done me good, and I have received new light. My husband has taken GLEANINGS over three years, and truly we would not know what to do without it. We have kept a few swarms of bees for several years, and I do love to watch them gather the honey, and work so busily. Sometimes I feel like telling them, after they have laid up a good share for themselves, to gather some for me. I like to help take care of them.

We shall try to winter about fifty swarms. If they live through the winter there will be work enough to do in the spring, and I shall endeavor to leave my work so I can help take care of the bees. Now, sisters, do not be discouraged, but work among the bees if you enjoy it. I think one of God's greatest blessings is the beautiful sunshine and good pure air; and if we are able to be outdoors we may enjoy this blessing. I think we can have better health by leaving our work and cares in the house, and work outdoors awhile. And surely good health helps to make good dispositions and happy homes. I think something as Mrs. A. does about these daughters who sit in the parlor with folded hands, or perhaps employed with a little fancy-work. Help mother do up the work, and then she can find time to sit down as well as you, or perhaps she can leave her work and watch the bees. It will do her good, and you too; for do we not receive a blessing in doing good to others, and trying to make them happy? Go about thy Master's business; find something to do. It may not be in the kitchen, it may not be among the bees; but God has something for each one of us to do. He is calling thee; arise, and go forth, trusting in his word.

HOW TO PUT UP EXTRACTED HONEY.

After reading friend Tweed's experiments with candied honey, on page 617, I must tell how I put up honey to have it keep. My way is pretty much the same as the one laid down in the A B C book. Sometimes I use bottles, but I prefer cans. When I use bottles I have the corks tight, and paste on paper over the cork, letting it come down over the bottle pretty well. I get my honey hot, but think it is better not to boil it. I have kept honey in this way from one to two years. I have put up honey in this way for over ten years, and I never fail to have good luck. Now as to the kind of honey; I did not know that it made any difference. I have put up several kinds. Last year I put up linden and I do not see why that was not as nice as the other. Perhaps there may be, but I have never put up any but that kept all right. I am inclined to think it is more the way it is put up than in the honey. **Mrs. Jennie M. Johnson.**

Rexford's Flats, N. Y., Aug. 14, 1886.

AN INTERESTING LETTER FROM AN A B C SCHOLAR.

A REMINISCENCE FROM ONE WHO IS ACCUSTOMED TO HOLD THE EDITORIAL HELM.

SOME men prefer to become somewhat acquainted before receiving an introduction; but I shall proceed to introduce myself to your many readers without further formality; and after I get through the ceremony they will be surprised to learn that so bright a light has been concealed under so small a bushel for so long a time without being discovered.

Some men were born great; others were born in Ohio, and to the latter class I belong. Nearly forty-five years ago I began to make trouble in this world by being born in a log cabin, situated in the township of Hanover, Ashland County. At the age of ten years my home was transferred to the broad prairies of Illinois. I have made repeated visits to the old farm, and of that particular locality the poet expresses my feelings in the following lines:

I love thy rocks and rills,
Thy woods and templed hills.

Yes, indeed, I shall ever cherish the place of my birth, and hold in sacred remembrance the hardy pioneers who made that wilderness to become productive, and a desirable place of residence. In fact, I sometimes feel as if I could adopt the language of the Babylonian captives when they expressed their deep longings to be released from bondage and return to their beloved Zion.

Was my father a bee-keeper? Of course, he was. Am I a bee-keeper? Of course, I am. There, now, you have the secret at last, and can judge at once what has constrained me to pen you these lines. Box hives were quite fashionable forty years ago, with variations in style and size. My father made a cupboard-shaped hive and put a swarm into it. The colony clustered in one corner, built lots of combs, but never swarmed, and never stored more honey than they seemed to need for housekeeping. Coming to Illinois he adopted the new system, took Gleanings, and ordered one of the first extractors of you ever introduced into this community.

In the course of time I caught the idea that I could keep bees; but having a wholesome dread of stings I delayed the attempt till some five or six years ago. I then bought a colony in a chaff hive, and have wintered a swarm in it successfully ever since. The first season I attempted to secure comb honey without putting starters in the sections, I failed of course. I learned better, and now I believe I can run a small apiary as well as the next man. But it requires study, experience, patience, diligence, and a perfect knowledge of the character, strength, and condition of every colony, as well as the nature of the season. I studied your A B C book morning, noon, and night; I read all the bee-literature I could get hold of, and I made personal tests of nearly every feature connected with the art of bee-keeping. I became infatuated with my bees—as much so as I was with telegraphy while acquiring a knowledge of that mysterious mode of communication; and even at this day, when the novelty of the occupation has worn off, I am thoroughly impregnated with enthusiasm during the honey season.

I keep bees simply for exercise, recreation, and—honey. This season I put in my best licks on a small scale. I had 17 colonies; worked them for all they were worth, and realized my most sanguine expectations in comb and extracted honey. Besides my own, I took care of the bees of a neighbor who can not be at home; and between the two I was kept more than busy during the swarming season; for, perhaps, in the middle of a "heavy" editorial the little boy would rush into the sanctum with the pleasing announcement, "Bees are swarming!"

Having acquired the art of bee-keeping and honey-raising, I am now engaged in working up a market for the nectar, and am succeeding quite well. In the first place, I advertise "judiciously." But, what is "judicious advertising"? some one may ask. Well, in my case it means to advertise in *my* paper. For bee-keepers, as a general rule, it may mean to advertise in Gleanings; and so you see every publisher of an advertising medium might feel inclined to define the meaning of that phrase so as to take in his own paper.

He who with bees would thrive
Will either bust or advertise.

Having advertised, results will follow in due season. Then give good weight and a pure article. Strange it is, that so much prejudice exists against honey. One customer said she wanted none made of sugar; another would buy only one section because it might sour. It may require some time to disabuse the people of these erroneous notions, but I generally succeed after one fair trial.

I weary your patience and crowd your space with what may interest nobody, therefore I bid you God-speed in your endeavors to benefit mankind by sweetening their lives physically and spiritually.

Naperville, Ill., Aug. 6, 1886. **D. B. Givler.**

Friend G., here is our editorial hand. Long may you prosper with the bees and with the editorial pen. I always felt as if it were a pretty good thing to be born in Ohio, but I did not exactly understand why till you made it so plain. I have sometimes wondered if anybody else knew exactly how it sort o' twists one when he is suddenly interrupted in the midst of something grand for humanity, by the announcement, "The bees are swarming," "There ain't any potatoes for dinner," or that the baby had fallen down stairs. If the editor is a Christian (and all editors ought to be, especially if they are born in Ohio), he must look pleasant, stop his editorial, and take the chances of being able to "catch on" where he left off when he gets the bees, potatoes, and baby righted. I am sure you are a Christian, friend G., or you would not love those lines about the "rocks and rills," as you seem to. Let us hear from you again.

HEADS OF GRAIN
FROM DIFFERENT FIELDS.

WHEN THERE IS AN ABUNDANCE OF HONEY IN THE FIELDS, WHY IS IT THAT MY BEES WON'T WORK?

FRIEND ROOT: - Can you tell me why my bees do not work more than they do? I often go out and stand by the hives (I have two), and I can't see a bee come out in five minutes, even on a nice day. They are hybrids and Italians, and I think the hybrids are the sauciest ones I ever saw. I get stung three or four times every day at one hive. Both colonies have good laying queens. I have one colony with 6 brood-frames in it, and one wide frame with sections, but they haven't 5 lbs. of honey in their whole hive to-day. They have made a little buckwheat honey, and a very little. There is about 50 acres in blossom within a mile of me, and about 3 acres on the farm I live on, within 500 yards of my bees; yet they do not seem to do much, while my neighbors' blacks are gathering a fine lot. I have my bees standing under two large maple-trees; do you think they have too much shade? The sun does not shine on the hives except from sunrise till 8 o'clock A. M., and from 4 o'clock till 7 P. M. They stand within ¼ of a mile from a lake that is a mile long and ½ mile wide. Do you think they are too near the water, and shall I lose many of them in it, if I should start an apiary here?

Monticello, N. Y., Aug. 10, 1886. F. SOMERVILLE.

It would seem that your hives are not very full of bees, if you can find a period so long as five minutes without any bees coming out or going in. A good strong colony in the middle of the day should have a dozen or two of bees constantly around the entrance, and more or less passing out and in every second.—We are well aware that buckwheat does not always yield honey, although it seems as if fifty acres ought to set them booming. I do not think you can have a better place for them than in the shade of maple-trees. I do not think the lake has much to do with it, unless it is in such a direction from the apiary that the prevailing winds are most of the time blowing from the apiary toward the lake.

STILL THE HONEY-DEW.

For the last four or five weeks there has been a continual flow of honey-dew, there having been no rain during that time in this part of the country. We did not have time this spring to provide hives enough for our bees, and have upper stories on only a few of them, therefore we are obliged to extract from the brood-chamber to prevent swarming, and it takes only a week or so for the bees to have every thing full of the black stuff. There are a good many flowers in bloom which I think contain a good bit of honey, but the bees seem to think honey-dew is the only thing worth gathering; but for my part I wish they would bring in something else, as I do not like it very well. Will this honey-dew get any better when fully ripened, and what ought it to bring, compared with white-clover honey? We fear we shall have some trouble in getting rid of it, as it is our first year that we have had any honey to sell, and shall have to establish a market for it, which I fear will be no small job with such black stuff. However, I have heard some folks say they liked it very well. Please let me know how it compares in value with other honey.

BUCKBUSH HONEY.

Have you ever seen any pure buckbush honey? If you have not I think I can send you some another year, unless the honey-dew rules it out as it has this year. We had some last year; and although it was quite dark I thought the quality very fine. We have a profusion of buckbush in this section, and I consider it a valuable honey-plant, as it comes at a season when very much needed here. S. E. MILLER.

Bluffton, Mo., July 31, 1886.

Honey-dew is improved by being fully ripened in the combs, like all other honey; that is, providing it is thin and watery when gathered. In regard to the price, I do not know what it will bring—much depends on the quality. I would offer it at about one-half the price of good honey. We have considerable of the buckbush in the garden, and the bees work briskly on it every morning, and have for several weeks; but we have never been able to test the quality of the honey.

WHY WON'T THE BEES ACCEPT A QUEEN?

I have two hives of bees, both swarms from the same hive, and neither of them will keep a queen. One of them I have given seven queens, and the other six; they will raise a queen, or keep one until she is about to lay, and then ball and kill her. There is no fertile worker, as there is no brood except what I give them. They are both strong in bees and honey, but they have no drones; but there is plenty in other hives. I keep them with plenty of brood. Can you give any reason for such actions? Do you think if I would give them a laying queen it would answer? RICHARD EDMUND.

Grand Crossing, Cook Co., Ill., Aug. 13, 1886.

Friend E., the conduct of the two hives you mention is very unusual. I would by all means try introducing a tested queen. Our remedy has been to give a colony plenty of brood and bees from another hive—that is, enough bees to induce the stubborn bees to behave.

CAN SECTION HONEY BE KEPT FOR ANY LENGTH OF TIME?

Can section box honey be kept any length of time? I have a number of 1-lb. sections that I should like to keep till winter, as they do not command a very ready sale now. **Mrs. E. Gaines.**

Milliken's Bend, La., Aug. 10, 1886.

You can keep section honey from now until Christmas, or even later, without any trouble at all, and without any apparent deterioration. As a rule, however, after it gets to be one year old or more it has to be sold at a reduced profit. The only conditions required in keeping it is to have it where it will not become damp, or get frozen. Of course, freezing does not, of itself, hurt the honey. When comb honey becomes very cold, and warmer air passes over it, moisture is liable to condense on the surface of the honey. This sometimes dissolves a portion of the honey and then it becomes sour. Besides, comb honey is liable to candy when kept a year or more, and this, as a matter of course, injures the sale of it more or less.

PLANT-LOUSE NECTAR.

My bees are at work on pond lilies, on the leaves, not on the flowers, and it does not make good honey—at least I do not call it so. I have had quite a number taste of it, and have found only one who liked it. The leaves are covered with black lice; and when the lice are the thickest, the bees seem to work the most. The leaves seem to sparkle like honey-drops after it is dried down. Where does it come from? Do the lice make it, or what is it? It is black, and muddy; you will say so when you get the sample; but it does not look so black when extracted as it does in the comb.

My bees are at work on the hickories some, but not so much as on the pond lilies. There are white lice on the hickories, and the honey is lighter than from pond lilies—at least I think the black is from the pond lilies, for the bees are at work on them more, and I am getting more black honey. The honey which I think comes from the hickories is clear and thick, but it is darker than white clover. I can not extract the light to get a good sample, for I have not got enough of it, so I will send a sample of the black, and will send a pond-lily leaf and the hickory. I should like to know whether the lice on the hickory are the same as the ones that made so much trouble a year or two ago. This is my first experience with that kind of honey, and I hope it will be the last. **A. O. Quick.**

Leoni, Mich., July 19, 1886.

Prof. Cook replies:

Dear Mr. Editor:—This is certainly plant-louse nectar. The pond lilies are thickly beset with black aphides, and the hickory leaves with green ones. The leaves also are thickly covered with the cast skins of the plant lice. That this nectar from plant lice is always pleasant and wholesome, as I had thought previous to a year ago, is far from the fact. I am now inclined to the opinion that, when unmixed with honey, it is often bitter and unwholesome. I am sure that, in some cases, I have tasted of a pure article which seemed quite palatable, and to my taste.

You remember what quantities came on the plants from Oregon a year ago. That was very pleasant. I have found the same true of nectar from the elm, cock's comb, gall-louse, and the larch-louse.

Mr. Editor, you have here a good reason to doubt again. Just think how wonderful for these lice to be on pond lilies. How did the colony get to this island home to establish itself? Did the little Lilliput take a swim? and if so, where was the compass to guide him to the desired spot? Again, does the louse work on the upper surface, exposed to the scorching sun, or beneath, to be washed and rinsed and doused at the mercy of the waves? It is the last place we should expect to be pre-empted by a plant-louse; but if to the liking of his louseship, it is certainly a good and safe place.

A. J. Cook.

Agricultural College, Mich., July 23, 1886.

DOOLITTLE'S WAY OF MAKING NUCLEI.

As it is difficult to start nuclei early in the season, I again tried the plan, and in several cases it worked well; but I soon found, as Ernest says, that the old bees in some cases return. I do not believe a safer way could be found to introduce a queen; but in one case after releasing them, the queen, a purchased one, took wing, and the bees began to return; and as they were taken from two hives they were killed when returning to the one, and in the other hive they balled a fine queen and killed her; and then the new queen, not having marked her location well, and it being quite windy, entered another hive, and was also balled. It is safer to release the bees directly on the frames instead of at the entrance, and should also be taken as far as possible from the hive they were taken from. When plenty of young bees are hatching, I don't think it worth while to bother with the plan. **Christian Weckesser.**

Marshallville, O., Aug. 2, 1886.

A HOME-MADE SOLAR WAX-EXTRACTOR; ANOTHER WAY TO MAKE THE REFLECTOR.

I see Prof. Cook is going to try to improve your solar wax-extractor, if he can. I have an improvement which is different from any I have yet read of. I made my box by nailing a bottom-board on an upper story of a hive, to make the box close. I made a frame to fit on top loosely, about three inches deep. I cut a groove in both upper and lower surfaces to receive a pane of glass in each side. I got two panes of glass cut to order to fit this frame, for 35 cts. On top of this double-glass frame for a reflector I made a large hopper, the lower part to fit on top of the glass frame closely all round the edge, and not touching the glass. The sides of this hopper are 14½ inches wide all round; bottom, inside measurement, 16×19¾; top, inside measurement, 30×42½ inches; corners beveled to fit. This gives a good slope to all the sides for reflection. I painted the inside a thick white coat; and if you think the inside of that box doesn't get hot on a sunshiny day, you would acknowledge it did if you were to put your hand inside. I arranged some cleats in the box to support a large circular tin pan to hold the wax to be melted. The pan, which is slanted at the lower edge, has the edge pressed down to form a spout. Underneath this spout I place a half-gallon tin vessel to catch the wax. I have several times filled this vessel during the middle of the day when the sun was hottest. The only fault I find with it is that my box isn't large enough square. I do not have enough square inches, yet it does admirably for small meltings. We have so little sunshine here in Louisiana that I don't know how many pounds it could melt in a day. If Prof. Cook will make a hopper reflector having the sides wide enough, and pitched a proper slope, and painted white, I think he will be able to concentrate a high degree of heat within the box. I have to handle my pan with a cloth to keep from burning my fingers. C. M. HIGGINS.

Hahnville, La., Aug. 3, 1886.

IS THERE ANY SUBSTITUTE FOR GRAPEVINES AS SHADE?

Would you be so kind as to tell me if there is any shrub or vine besides the grapevine that will shade the hive, and be forage for the bees? Where could I obtain seed or plants, and about what cost?

J. H. S. CRONK.

Burgersville, Ont., Can., July 22, 1886.

Friend Cronk, there are many plants and vines that will answer about as well as grapevines. We prefer grapevines because they are permanent, and also handsomer than any other plant that we know of, besides the fruit they bear. Sunflowers, lima beans, tomatoes trained on trellises, and a good many other plants, are used under certain circumstances.

FASTENING SECTIONS TOGETHER WITH A TWISTED STRING.

Bees are doing exceedingly well. I have never seen so good a honey season. I have been trying friend Doolittle's plan of putting queen-cells in a tunnel shaped wire cage, and it is a success. I have also been cutting my sections, to let the bees through every section without going back into the brood-chamber; but I don't know yet the result. Can you tell me how to fasten sections close together so as to stay? I have been puzzled a good deal; but I will tell you how I did it. I use 21 sections on a rack. I set 7 in a row, and take a strong manilla string and tie around to hold the glass in, then take a small stick and twist the string as tight as it will bear, and fasten it; and when the 3 rows are completed I set them on a rack and twist a string around the whole and press them together. This keeps them very close together, but it is too much work. E. S. HANSON.

La Otto, Noble Co., Ind., July 5, 1886.

Your plan of tying up sections with a stout string, to hold glass and all together, is quite old. and I believe the objection to it is usually about like yours. See the plans for cases and crates in our own price list and the price lists of other dealers in supplies as well.

DISTINGUISHING DIFFERENT RACES OF QUEENS.

Referring to your conclusion on page 614, that I can not always distinguish the difference in appearance between Carniolan queens and hybrids, I admit it; and, further, I can't always distinguish between Carniolan queens and Italian queens. Furthermore, you know you can not *always* distinguish between Italian queens and our common black queens. The fact that some imported Italian queens are darker and meaner looking than *some* black queens has certainly long ago been established beyond question; and if it has not, I should like to have the pleasure of putting some specimens in your hands, to decide by *appearances*. There are some Carniolan queens with bronze-colored abdominal rings that I have not seen in any other race; there are others raised from the same mother, that I could not distinguish from fine Italian queens, and still others I could not distinguish from our "black" queens. I believe I can not be deceived about a colony of Carniolan *workers*—I am sure I can not. S. W. MORRISON, M. D.

Oxford, Pa., Aug. 2, 1886.

WON'T ACCEPT A QUEEN, BUT BUILD QUEEN-CELLS.

I found a colony that I can not get to accept a queen. I caged an Italian queen in their hive in a Peet cage, and they refused to accept her all the time. They ball her every time she gets out, and I have her to cage again. They build so many queen-cells that I get tired of cutting them out. The second day after I had queened them I found 63 queen-cells on one frame of fdn. There were 49 on one side, and a good many on the other frames that I didn't count. These were blacks, but I don't think your Holy-Land, Cyprians, or any other kind, can beat them building cells. C. F. GRUBB.

Bridge, Davidson Co., N. C., July 1, 1886.

Sometimes a colony of bees seem determined to rear a queen of their own, instead of accepting one. In that case we generally humor them; that is, we often conclude that we shall get along about as fast to let them do it in their own way.

A MACHINE FOR CLEANING PROPOLIS OR WAX FROM THE TOP-BARS OF FRAMES.

I send you a rough model of a scraper to clean wax and propolis from frames without removing them from the hive. The handle is 7 inches long, and the edge 1½ inches long. I took a piece of a saw-blade for the edge and made the pocket of tin, about three inches deep; it will hold all there will be on almost any hive. From 70 hives I got enough to make wax enough to pay for two or three scrapers. If the frames are all wood they will be firm enough to scrape without holding; but if they have metal corners they will have to be held with one hand. If you think this is worth giving to the public, they are welcome to it. JOHN WOOLSEY.

Bedford, N. Y., July 22, 1886.

I will explain to our readers, that the model referred to is a piece of tin, bent in such a way as to make a sort of pocket. The wooden handle referred to is set into the pocket, and fastened by means of wire nails from each side. When you draw it over the top-bar of a frame, the wax and propolis roll up and go into the pocket so as to amount to quite a saving of time. The question now arises, Do we want our top-bars scraped off clean? Many bee-keepers, and friend Doolittle among the rest, say they do not want the top-bars scraped off — at least friend D. said so some years ago when he paid us a visit. If left on, it gives the bees a passage over the tops of the frames; and while there is a honey-yield it will be filled in almost at once, even if scraped off. Of course, these remarks apply to hives where a cloth or enamel sheet is used over the frame. With honey-boards like Heddon's and others' I believe the top-bars are kept clean; and if the honey-board is kept down in place, probably no accumulations are found on the top-bars.

WHY IS SO LARGE A PERCENTAGE OF MY QUEENS NOT FERTILIZED?

Can you tell me why I lose so many queens at about the time they ought to become fertile? Out of 53 apparently good virgin queens, in full colonies and nuclei, all from swarming cells, only 31 became fertile; all the rest disappeared at about the time I expected them to begin to lay. Is this not an unusually large percentage of loss, or is it so with every queen-breeder? I thought for some time the trouble was in the wrong arrangement of my hives; but it seems not to be the only cause. I have my hives in rows, 12 feet apart one way, and 3½ ft. the other way, so arranged that they "break joints." My hives are large chaff hives, each of which has a 2-frame nucleus in the upper story. This gives me many more nucleus hives than I need, so I use only every fourth or fifth. This, I thought, would prevent the young queens from entering the wrong hive; but the result was, that in some nuclei four queens were fertilized, while in others just as many virgins were lost. With full colonies I have about the same trouble.

Julius Johannsen.

Port Clinton, Ottawa Co., O., Aug., 1886.

Friend J., your hives are too near each other, and too much alike. See what I say in the A B C book about the importance of having them placed toward the different points of the compass, even when they are 7 feet from center to center. Try one nucleus off by itself for a few days somewhere, and see if you do not get better results; and another time and another season you may have good results just where you are; but I should say that 3½ feet is much too close. The bee-keeper who has well-made, nicely painted hives, is more apt to have trouble in this respect than one who has his bees scattered about in hives of all sorts and sizes, because, in the former case, each hive looks exactly like its neighbor.

RENOVATING FOUL-BROODY HIVES.

Having lost all my bees by foul brood, I melted up and boiled all the honey and wax, and such fixtures as would go into a wash-boiler. My hives being too large, I took a length of 18-inch smokestack, set it on end over a grating of iron scraps, scooping the dirt away on one side, for a draft. I then built a fire in it and set one of my hives, bottom up, on top of the pipe, protecting the edges of the hive by a strip of sheet iron laid under them on each side. I regulated the draft by opening and closing it with bits of sod. In a few minutes the hot smoke was issuing from every crevice, and the melted propolis dripping down all around. Some of the hives took fire inside. I threw them right side up on to the ground, and dropped a little water on to the bottom-board, when the hive would instantly fill with steam, and smother the flames. The bees do not seem to dislike the charred wood to live in, and I have found no trace of foul brood among them yet. I got 6 three-frame nuclei from the South about May 15, from which I now have 9 good strong colonies, some of them storing honey in boxes.

HONEY-DEW.

We are having our first experience here with honey-dew. About two weeks ago it appeared on balm-of-Gilead, elm, and burr-oak trees, which dripped so as to smear the sidewalks in places. *Now* the black oaks are covered with it. I find the leaves have a great many little green plant-lice on or under them. I thought I would tell you how, with a few cents and three or four hours' work, I made a machine for perforating frames for wires—capacity 200 strips per hour, but conclude for this time.

Geo. H. Patch.

Stevens Point, Wis., July 19, 1886.

Thank you, friend Patch, for your description of the way you renovated your foul-brood hives. In Our Own Apiary for this issue you will see that we employed a similar plan, only we used steam.

A NEW USE FOR THE SMOKER.

The Williams folks desire me to thank you heartily for the smokers, and so do I. Now I have the job of reading the "Dose of Truth" to them. Although I have always held smoking to be wrong, and chewing too, I never saw such reasons advanced as I find in your pamphlet. I think it should be more generally distributed. The Williamses have found a new use for their smoker; and had I been aware of it two months sooner I would have ordered a thousand or so. I know I could have sold that many. Let me explain: This is a great mosquito country, especially now in the rainy season. Although netting and cheese-cloth bars are in use, they are warm and disagreeable to sleep under. Now, a few rags in the smoker, a few minutes before retiring, set on fire, and the smoke well puffed in all corners, causes the mosquito to leave for that night. Such is also my experience, and I would not now be without a smoker for its cost for a single night.

Fort Ogden, Fla., July 20, 1886. F. Schindel.

THE PROGENY OF MISMATED QUEENS.

I have a dollar queen, one year old, bought of Wm. Cary. All I bought of him with the exception of this one are very nice queens. Her bees are about one-third black, to all appearances, even the old ones, temper not excepted. One-third have two bands, and the other third are very finely marked Italians. This is something new to me, and I should like to know if it is very common, and also how it can be so.

5—H. P. Langdon, 30—50.

East Constable, N. Y., Aug. 3, 1886.

It is not unusual for mismated Italian queens to produce bees variously marked, from real black bees to three-banded Italians. As a general thing, however, a pure queen mated with a black drone will produce one and two banded hybrids.

BEE-KEEPING IN UTAH.

I am doing what I can in a modest, feeble way, to advance the interests of the bee-business in this village of over 2000 inhabitants. There are at present over 260 colonies of bees here in the keeping of 7 different persons, besides 97 colonies of my own, which are getting too large a number for one little old man in one location to handle. I have therefore laid the foundation of another apiary, located very high up in the mountains, designing thus to lessen my labors here at home. This new location is in the midst of a little world of wild blossoms; one succeeding another the whole summer, from the moment the snow is off the ground in spring until frost cuts down all in the fall. Indeed, I have seen blossoms fully defined and developed, but closely folded, lift their heads throughout the fast-melting snows of spring, and in a minute or two would appear, while I yet stood wondering at the thing of life, a beautiful and complete wild blossom standing just in the edge of snow. From these wild blossoms bees gather large stores of honey, some of which I will send by mail in a small bottle. This honey was deposited in old combs carried from here in the winter, wherein were some grains of old honey, a few of which you can see in the bottle, so it is not entirely wild honey, but enough so that it shows the peculiar flavor which I wish you to taste and examine; and, if you have no objections, give me your opinion as to its salable qualities among those well used to choice honey. Perhaps what is pleasant to us is not pleasant to others afar off, reared in a different climate.

O. B. HUNTINGTON.

Springville, Utah, July 20, 1886.

Friend H., the flavor is certainly peculiar, and to me it is very pleasant indeed. I should think the honey would command a good price just on account of this flavor. The same, or something quite similar, has been submitted to me once before. If you will send us, say, a couple of the plants, we will have our botanist name it.

A CARD FROM H. CHAPMAN.

Mr. Editor:—It has not been my purpose to say or write much about or offer any seed of my honey-plant for sale until after the report of the committee appointed by the North-American Bee-Keepers' Association to examine and determine its value as a honey-plant. The committee met at my place July 28th (all but Mr. Manum, of Vermont, who was prevented by unforeseen circumstances). The committee present were A. I. Root, of Medina, Ohio; L. C. Root, of Mohawk, N. Y., and N. W. McLain, of Aurora, Ill. They will make their report as a committee at the next annual meeting of the Association, to be held at Indianapolis, Ind., Oct. 12th, 13th, and 14th. But since the meeting of the committee at my place, members of it have written so favorably of the plant in the bee-journals that I have received a large number of letters of inquiry, requiring so much of my time to answer that I deem it proper, through the bee-journals, to say, I have no seed but the present season's growth, which will not be ready to send out until about the 20th of October next. I purpose to advertise in the bee-journals after the report of committee at Indianapolis. Seed will be sold in half-ounce, ounce, two-ounce, and four-ounce packages. The price will be determined after the report of the committee. All desiring seed are referred to my advertisements, which may be found in all the leading bee-journals in America, after the report of the committee at Indianapolis.

H. CHAPMAN.

Versailles, Catt. Co., N. Y., Aug., 1886.

RATTLESNAKES AN ENEMY TO BEES.

Dear Brother:—The bee-moths got into the weak swarm I had, and they are about used up. I have just put the old combs in the solar extractor, and now have a nice cake of wax. In lifting the hive to move it, the bottom-board stuck to the hive and I found a big rattlesnake coiled up under the hive. The sudden daylight surprised him, and he surprised *me* too; but I recovered myself first, and killed him. I have taken off 100 lbs. of comb honey from my two hives, and the bees are working yet.

THE SIMPLICITY SECTION IN CALIFORNIA.

I took 74 sections into town. Harbison honey is selling at 5 cts. per lb. One of the leading honey-buyers offered me 7½ cts., and said if mine had been whiter he would give me more. One objection is, that on or near the coast the honey is darker than further back. The style of your section is the first they ever saw. Even Mr. Harbison thought they were nice. I am going to hold it for a higher price.

There was a swarm of bees went over the barn today. I thought it was too late for them, or I would have had out some more decoy hives. M. S. ROOT.

San Diego, Cal., Aug. 9, 1886.

Brother Marsh, excuse me for thinking that it was the rattlesnake instead of the moths that injured your weak swarm. We have had several reports of snakes getting under bee-hives and catching the honey-laden bees as they came in, until the swarm was too much depleted to take care of itself. Very likely the moths would come in as a consequence. No wonder you were a surprised lot of you.—I am glad to hear that you are beginning to make modern bee culture "go" a little; but I am greatly surprised to know that so large a city as San Diego should be unacquainted with the one-pound Simplicity section.—I should think it would pay to save absconding swarms in any month of the year in your mild climate.

A SOLAR WAX-EXTRACTOR FOR A NICKEL.

I think I must describe my wax-extractor. It works to perfection, and is cheap. It is taken from your 5-cent counter—a tin wash-basin. Punch the bottom full of ⅛-inch holes; set it in top of a stoneware butter-jar, and put a glass on top. Throw in the wax scraps. A wooden frame around the glass would keep it from sliding off or breaking easily, but it is not necessary. I also have a wooden cover to the jar, with a beveled hole in the top, which allows the extractor to be tipped toward the sun.

JAMES EVANS.

Schaghticoke, N. Y., Aug. 24, 1886.

Very good, friend E.; but it seems to me that your stone jar and pane of glass ought to count something in footing up the expense of the apparatus. Wouldn't one of our 15-cent strainers answer better than the wash-basin? They are about the size of the basin, with an opening at the bottom, covered with brass strainer cloth. The polished sides of the basin would help to reflect the sun.

CARBOLIC ACID.

In the *British Bee Journal* for Aug. 12, 1886, we find the following:

> I have just made my first experiment with carbolic acid, in order to remove a super, and have been any thing but successful. I made a square cage of iron gauze, inserted in it pieces of sponge saturated with the acid, and placed it inside my Bingham smoker, then proceeded to drive the fumes into the super, at the top, but it produced not the slightest effect so far as I could see, for the bees rushed out as fast as they could from between the sections; and when, after waiting a short time, I removed the super, my hands, though perfumed with Calvert's No. 5, received more stings than they have enjoyed for a long time. I had on a veil, or I should hardly have been able to see to write this. I am greatly disappointed, as I had looked forward to getting rid of the trouble of the smoker, with the inconvenience of its frequent extinction.
>
> J. COVE JONES, *Loxley, Warwick.*

This accords very well with Mrs. Chaddock's experience in a late issue. May be, however, that both of the above parties have failed to comply with all the conditions required. We have ordered one of the smokers from the inventor, and will report promptly as soon as it arrives. We are informed that it is now on the way.

HOW MUCH SHOULD BE FED A COLONY DAILY DURING A DROUGHT?

Bees were held back by a drought of some 60 days. But three very heavy rains have turned the tables. Does it pay to feed continuously straight through such a drought? If so, how much per day, per colony, etc.? W. M. BOMBERGER.

Harlan, Iowa, Aug. 2, 1886.

Friend B., I think it does pay to feed continuously right through a drought, especially if you wish to increase the number of your stocks. I do not know how you are to give a definite quantity of bee-feed daily, so much depends on the strength of the colony, and they almost always get more or less from the fields. The thickness of the syrup has also something to do with it. I would suggest a teacupful a day of syrup containing about twice as much water as ordinary honey; that is, if I used honey for feeding I would dilute it first with an equal quantity of water, especially if I wished to promote brood-rearing.

REPORTS ENCOURAGING.

A GOOD YIELD; ARE BEES APT TO DIE IN WINTER AFTER A HEAVY HONEY-FLOW?

I STARTED with four colonies of bees this spring, and from three frame hives I have taken 250 lbs. of comb honey, and they have 32 sections more, nearly filled, apiece. My box hive has filled only two boxes, about 20 lbs. This has been a wonderful season for bees here. I went according to your instructions in the A B C book, and kept my bees at work by lifting up the bottom and driving them in and giving them more room whenever they began to hang out; and the consequence is, that I got a good deal of honey and only two new swarms; but if I can sell my honey for what it is worth I will buy bees by the pound in the spring. Honey is selling for 12½ cts. for comb, and 8 cts. for extracted. Every one's bees have done well, especially those in frame hives. I took 150 lbs. from one hive (hybrids), and still they are at work. There is a great deal of buckwheat sown this year, and we expect quite a little honey from that. Last year was so wet that bees did scarcely any thing except to gather pollen and raise bees; and there was such a rank growth of heart'sease and late honey-producing flowers that the average loss during the winter was about 1 in 30. Now I wish to ask you if next winter will not be pretty hard on bees on account of the great amount of work they are doing this summer? and what shall we do to make our colonies strong for winter? I have an idea that, when there is a great flow of honey, bees do not raise so many young, and that those that remain in the hive during winter are more or less exhausted from field work, and would die before spring, and leave the colony so weak that it would die. L. W. RICH.

Lamont, Buchanan Co., Ia., July 27, 1886.

Friend R., I do not think bees are more apt to die after a heavy flow of honey, but, rather, to the contrary. The Italians will, however, fill their combs to such an extent as to prevent brood-rearing where room is not given them in which to store their surplus honey. But bee-keepers nowadays are seldom known to neglect giving the bees storage room when honey is coming.

$7.00 CLEAN CASH FOR A SINGLE CRATE OF HONEY.

I have kept bees for quite a number of years, and never saw a movable-frame hive until last spring, and then I made it myself. Mr. E. H. Cook, of Andover, Conn. (of course, you have heard of him, for he has sent you a good many orders for goods, and a tiptop upright honest man too), sent me the dimensions for making the L. hive, and then I bought two tested queens from him, and had him come and transfer my blacks into the movable-frame hives for me. I find I can get some good honey now which I never could do in the common box hive; and, furthermore, I never sold a pound of honey before I had my bees transferred; but now I can sell all the box honey my bees can make. There was a merchant who came to my house last Tuesday to buy some honey of me, and I took a section case off from one of my hives, and he gave me $7.00 in clean cash for it. That was 25 cts. per pound for it, and he wanted all I had to spare this season at the same price. L. I. WALDO.

Merrow, Tolland Co., Conn., July 30, 1886.

350 LBS. OF HONEY FROM ONE COLONY.

Bees have done well up to date, but I think the honey season is over. Best yield from one swarm, extracted honey, to date, 350 lbs. SAMUEL LISTER.

Newton, Iowa, July 12, 1886.

REPORTS DISCOURAGING.

JUST PULLING THROUGH.

BEES are just pulling through. I shall have to feed sugar to winter them, if they don't do better. I am out nearly $100 this year; and if I had to look to the bees for it, I never could make a start in the way of paying my debts. But, thank the Lord, I have more than bees to look to. A. L. LIGHT.

Groveland, Ark., Aug., 1886.

LESS THAN 100 LBS. FROM 20 COLONIES.

The honey crop amounts to nothing with me this season. Out of twenty colonies, spring count, I got less than 100 lbs. of honey, and I shall have to feed several hundred pounds of sugar for winter. I now have 39 colonies in a thriving condition, and am not a bit discouraged. L. H. ROBEY.

Worthington, W. Va., Aug. 4, 1886.

A POOR SEASON IN ENGLAND.

This has been a very bad season for business, as June was so very cold. C. N. ABBOTT.

Fairlawn, Middlesex Co., Eng., July 21, 1886.

NOTES AND QUERIES.

BEES NOT WORKING ON BASSWOOD.

THE honey season has been a good one here, but is just about closing, owing to dry weather. I have three basswood-trees in my yard; but this year the bees paid them very little attention. This surprised me some, as the trees were never fuller of bloom.

Woodstock, Ill., Aug. 2, 1886. A. W. CUMINS.

CHAPMAN HONEY-PLANT.

Chapman honey-plant lasted only from July 20 to Aug. 10. Rocky-Mountain bee-plant is still in bloom, and will be till frost. A. J. COOK.

Agricultural College, Mich., Aug. 17, 1886.

HOW TO KILL CANADA THISTLES.

The easiest way to kill Canada thistles is to cut them low in the ground, and pour about a gill of coal oil on the stump. This treatment has succeeded well in Northern Indiana, where the seeds are brought by cars from Canadian railroads.

Vincennes, Ind., July 17, 1886. E. BURKE.

A CORRECTION.

In Aug. 1 GLEANINGS, p. 620, I was surprised to see in my article, 6th line, "Cast skins of spiders;" it should be "Cast skins of aphides." This showed that lice had been there. I like the solar wax-extractor *very* much. A. J. COOK.

Agricultural College, Mich., Aug. 4, 1886.

TWO QUEENS IN A CELL.

I send you by this mail a curiosity. A queen-cell I had put into a nucleus did not hatch; and on opening it I found two full-grown queens. Was this ever known before? What made them die?

Bristol, Vt., July 4, 1886. E. O. TUTTLE.

[I think we have had reports before of two queens in a cell. Probably they died because there was not sufficient nutriment or sufficient room for both of them.]

SHALL WE SUPERSEDE QUEENS WHEN THEY ARE THREE YEARS OLD?

I have a nice queen that will be three years old in August. I have been advised to supersede her on account of her age. Shall I do it? S. R. FUSON.

Rockville, Ind., July 12, 1886.

[Friend F., I would supersede any queen that did not keep her brood-nest full, no matter what her age; and I would keep any queen that *did* keep her brood-nest full, no matter what *her* age; that is, I would not destroy any queen because she happened to be so many years old. Make her *work*, rather than her *age*, decide the matter.]

BLACKS WORKING ON RED CLOVER.

I have seen the blacks working on red clover as thick, seemingly, as the Italians. There was lots of buckwheat in blossom too. Are the Syrians, Holy-Lands, and Palestines all the same race of bees, or are they all different races? White clover and basswood were injured by the dry weather a good deal here; basswood lasted only about five days.

CLARENCE W. BOND.

Jackson, Mich., Aug. 16, 1886.

[Friend Bond, the Syrians, Holy-Lands, and Palestines are so nearly alike that we might as well call them one and the same thing, although the bees from certain localities give much better results than those from other localities.]

SEPARATORS NOT A PREVENTIVE TO QUEENS LAYING IN THE SUPERS.

I have a number of times found brood in sections where separators were used, so nearly as often as when they were not, that I have about decided that separators or no separators makes but little difference. This matter of brood in sections has become such a nuisance to me that I am going to use queen-excluders pretty generally. GEO. F. ROBBINS.

Mechanicsburg, Ill., Aug., 1886.

OUR OWN APIARY.

AN IMPROVEMENT IN CHAFF-HIVE COVERS.

JUST after the honey-flow we have always been annoyed by a few stray robbers tugging at the ventilators of the chaff-hive covers. At such times there are a few bees which seem to persist in minding every one's else business but their own; and whenever a hive-cover is raised they will dart down into the hive. Situated as we have been with foul brood in our apiary, a few such bees could do a vast amount of harm. Passing through the apiary one day I felt particularly vexed to see a lot of these shiny-backed fellows trying to pass through the ventilator-holes to the chaff hives. It is true these holes were covered with wire cloth on the inside; but why should those bees try to get through it? I then remembered that bees will feed each other through wire cloth. It was evident, that the inmates of the chaff hives were feeding the robbers on the outside through the wire cloth, otherwise the little lovers of ill-gotten gains would have gone home. I accordingly instructed the apiarist to tack wire cloth on the *outside* of all the chaff-hive ventilator-holes in the apiary. This would make ⅜ of an inch space in each ventilator, between the strips of wire cloth. When the chaff-hive covers had been so fixed, the result was very satisfactory; for not a robber would bother himself with those ventilators; in fact, we have wondered why we had not done it before. Try it, brother bee-keepers, and note the results.

We are sometimes annoyed by bees getting under the covers of Simplicity hives; and it has occurred to me, Would not this trouble be aggravated if the union of the cover and body were made by simply a plain unbeveled edge? The beveled edge of the Simplicity will permit of considerable warping of both body and cover, and yet not permit any robbers to get into the hive. Where plain edges meet it has seemed to me that a very slight degree of warping would start robbers. I may be mistaken. Perhaps some one can inform me to the contrary or otherwise. The plain edge possesses some very important features, I am well aware; but I will not take time to mention them here.

THE SIMPSON HONEY-PLANT.

Whatever may be said in praise of the Chapman honey-plant, it would be hard to excel the Simpson in many respects. The bees have been roaring on our patch from morning till night ever since the fore part of July. If you should stand at the end of one of the rows you might see hundreds—yes, thousands—of bees flitting around the little cup-shaped blossoms. Is there any sweeter sound to the bee-keeper than the happy hum of his little servants? How different from the roar when bees are robbing! When I take visitors down to see our carp-pond I always take special pleasure in showing them our patch of Simpson honey-plants. The Chapman honey-plant may yield more honey in a short space of time; but as the Simpson honey-plant continues yielding for two or three months, the aggregate amount of nectar secreted by the latter might equal that of the former. I have thought some of covering a whole Simpson plant with mosquito netting, and allowing it to remain for two or three days. At the expiration of the time, would the cups be running over? I would have tried the experiment, but our plants are from 6 to 10 feet high, and it would be a rather difficult matter to completely cover the plant, branching out as it does like an evergreen. It just occurs to me to put one of our folding tents over a small plant. Well, I will tell you the results next time.

BEES WORKING ON BUCKWHEAT.

Three weeks ago we planted about three acres of buckwheat; and to-day, Aug. 27, it is in blossom, and the bees are working on it at a pretty good rate. I noticed the same happy roar, of which I spoke a moment ago. About 10 A. M., on account of the large number of colonies in this locality, the bees stop work and commence early the next morning.

POLLEN AND MUDDY WATER.

Pollen-gathering continues the whole day. This, together with the buckwheat in the morning, keeps the bees in our apiary just now out of mischief. Yesterday, the 26th, about 2 P. M. I noticed the bees going in great droves south of the apiary. I was not certain whether they were working on the corn or getting water from the creek running about 200 yards from the apiary. Starting in the direction the bees were flying, I found that they were sipping at the muddy water in the creek, in large numbers. No doubt the large amount of pollen being gathered necessitated a good supply of water. As we have been obliged to discontinue the sale of queens since the first appearance of foul brood, we have none but laying queens. The consequence is, that brood-rearing is being carried on more extensively than ever before. It is, therefore, nothing strange that the traffic in pollen and muddy water is brisk.

UNITING SO AS TO MAKE THE BEES STAY IN THEIR NEW LOCATION.

In the evening, when the bees are all in the hive, we unite the two in the ordinary way. At the time we do this we reserve a frame of unsealed brood, and place it back in the hive whence it came. This is done to catch a good many of the old bees, which will be sure to return to their old location. Said bees and the frame of brood are allowed to remain in their old home from 24 to 48 hours, during which time the new order of things, together with the loss of their queen, seems to disconcert them and puts them in a condition to accept any circumstances whatever. At the expiration of a day or so this frame of brood and bees are put back in the colony in the evening where they were first placed. We find in practice that this second returning is pretty sure to make all the bees stay, though sometimes perhaps a dozen old worn-out fellows (not much use) are so wedded to their old home as to go back again even then.

When uniting into chaff hives we find it quite an advantage to put all the bees of the new colony on combs in the upper story, just above the colony already occupying the hive. The brood is placed below in the body of the hive. It will then be a couple of days before the bees in the upper story will go below. When they do they will be more apt to stay in their new location. The returning bees are then caught as before.

HOW WE DISINFECT CHAFF HIVES BY STEAM.

Shortly after foul brood broke out among our bees we had about a dozen chaff hives which had contained diseased colonies. These were set in a row, conveniently located to a steam-pipe. In the evening I donned an old apron belonging to one of the saw-room hands, and proceeded to business. Having attached about ten feet of rubber hose to the aforesaid pipe I shoved the hose through one of the ventilators of one of the hives. The hive-cover was thus permitted to fit tight, and the only exit for the steam was at the extrance — the steam passing from the top of the hive to the bottom. With a boiler pressure of 50 lbs., I let each hive in turn roar and steam from 15 to 20 minutes. In one instance I approached a hive immediately after thus steaming, and raised the cover, being a "lettle" curious to see how hot it was inside. When the scalding vapor puffed into my face and on my hands, I didn't say any thing—no, not so much as "ouch;" but that cover went right back on to the hive, and that right speedily too. I then concluded if the germs of foul brood (if there were any in the hive) were submitted to such a dose as this for 15 whole minutes that they ought to die; if not, they were exceedingly tough. At any rate, if boiling water will kill the disease, I am morally certain *these* hives were disinfected. However, as we have tried to follow the policy of not running any *possible* risks, we shall not put bees in these hives in our home apiary. We propose to use them in an apiary which we intend to locate next year away from home, where we will run more especially for honey. If these hives should give the disease there among a few colonies, no very great damage can be done.

FOUL BROOD UP TO DATE, AUG. 31.

In spite of us, as stated in another column, a few more cases have developed. However, when the apiary was last gone through, only one diseased colony was found, and that was in the very early stages. ERNEST.

GLEANINGS IN BEE CULTURE.
Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, SEPT. 1, 1886.

If ye abide in me, and my words abide in you, ye shall ask what ye will, and it shall be done unto you.—JOHN 15: 7.

WE have to-day, Aug. 31, 5887 subscribers — a gain of 73 over last month. Many thanks, friends, for your kind support.

A YEAR OF GLEANINGS FOR 15 CENTS.

ALTHOUGH we have sold a good many, we still have a large stock of bound volumes of GLEANINGS for 1876, of which we told you about on page 595. We will dispose of them for 15 cts. each, or 25 cts. by mail postpaid.

FOUL BROOD, AND ONE OF THE DIFFICULTIES IN GETTING RID OF IT.

On page 700 of this issue, friend Long tells us that a good flow of honey may cover up the honey in the hives containing foul-brood germs, so that it will disappear for some time. When this new honey is consumed, however, so that they get down to the old honey in the bottom of the cells, foul brood makes its appearance again. Now, with such a state of affairs I can hardly understand how phenol or any thing else can reach the whole of the trouble. Throwing the honey out of the combs and scalding it, then making the bees clean up such combs and consume the honey before they commence brood-rearing again, might do it; but is it not about as cheap, all things considered, to destroy all combs with their contents, when it is known positively that foul brood is in the hive?

MR. THOMAS HORN.

We are sorry to be obliged to say, that, up to date, Mr. Horn has done nothing toward making his promises good; and, so far as we can learn at present, nothing can be recovered from him by legal means. A few of the friends have seemed to think we ought to hold ourselves responsible because we admitted him into the advertising columns of our journal. Inasmuch as he was responsible, and was so spoken of by his bankers at the time we received his advertisement, we do not feel called upon to make these losses good. Where a man fails by misfortune, or even by deliberate plan, it is quite a different matter from one who gets into the advertising pages of a reliable journal by the carelessness of its proprietors, and thus victimizes its readers. In the case of Mr. Horn, it seems to us that we took all reasonable precaution to find out about him before we received his advertisement; and let it be remembered, that he did business squarely and honorably for a good many months.

ITALIAN BEES IN IOWA.

60c to 85c per lb. Queens, 30c to $1.75, according to kind and time. Also bee-supplies and honey. Order from free circular. **"How to Raise Comb Honey,"** an illustrated pamphlet, just out, price 5 cents. Address OLIVER FOSTER,
13tfdb Mt. Vernon, Linn Co., Iowa.

FOR SALE CHEAP.

100 Simplicity chaff hives, good as new, all painted white; about 1500 combs (nearly all worker), 100 chaff pillows; 100 surplus hives; 100 division-boards, 40 of which are feeders; 100 "Hill's device;" honey-tank holding 1100 lbs., lined with tin; extractor; 100 enameled cloths; 40 colonies of bees, with stores enough for winter. Will sell the whole, delivered on board of cars, for $300; cost me $800.
17d R. W. KEENE, Croppers, Shelby Co., Ky.

4 H.-P. ENGINE FOR SALE.

A Bargain for the man who is in need of a First-Class Engine and Boiler.

This is one of B. W. Payne & Son's Eureka engines, the same that we advertise in our catalogue. It has run 3 months since it was new; has had a 10-foot galvanized-iron smoke-stack added, and is in perfect running order. The man who is holding it had to put in a larger one to meet the demands of his trade. The price of a new engine and boiler complete, no stack, is $275.00; but to make a quick sale we will sell this one with the stack for $225.00, free on board cars at Higginsville, Mo.

A. I. ROOT, MEDINA, OHIO.

STORE-KEEPERS, LOOK HERE!

"HANDY" POSTER-HOLDER. Takes the place of tacks, paste, and pins. By mail, 1 pair, 5c.; 3 pr., 10c.; 5 pr., 15c.

DISSOLUTION NOTICE.

Notice is hereby given, that the partnership heretofore existing between E. M. Kennedy and R. B. Leahy, manufacturers of and dealers in apiarian supplies, has been this day, by mutual consent, dissolved, E. M. Kennedy retiring. All liabilities of the firm are payable by R. B. Leahy, and all bills due the firm are payable to R. B. Leahy, who now owns and controls the business.

ELI M. KENNEDY,
R. B. LEAHY.

Higginsville, Mo., Aug. 25, 1886.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or $2.00 per annum, when given once a month, or $4.00 per year if given in *every* issue.

$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or $2.00 per year.

Those whose names appear below agree to furnish Italian queens for $1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for $1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

KIND WORDS FROM OUR CUSTOMERS.

Have received the 500 sections all right. I never saw a *nicer* lot. G. W. CANFORT.
Bloomingburg, N. Y., July 16, 1886.

The goods came in A 1 condition, and please me very much. I can hardly imagine how I got along without the wheelbarrow; while the same scale which you sent costs *here* $2 more.
Verdugo, Cal., June 27, 1886. G. B. WOODBURY.

PLEASING.

Please, sir, would you please to be so kind as to please to send me a *honey-jumble* by mail, if you please? C. C. MILLER.
Marengo, McHenry Co., Ill., June 23, 1886.

OUR REVERSING DEVICE PLEASES.

I now have about 200 pairs of your reversible wires in use, and like them very much. I send order for another 100 pairs. LEWIS P. BILLINGS.
Bloomington, Ill., July 31, 1886.

Thank you for sending journals so promptly, though not prepaid. Your faith in men's honesty must embrace all mankind, and reach right around the world. J. WOOD.
Ohaupo, Auckland, N. Z., May 19, 1886.

The goods came all in good shape. Every thing gives so good satisfaction I can not praise any one thing in preference to the others, unless it be the carpenter's level for 50 cts., which is a thing of beauty indeed for so small a sum of money.
G. E. HUTCHINSON.
Rogersville, Mich., July 29, 1886.

Allow me to thank Ernest for the work he is doing in GLEANINGS, and ask him to continue to tell us about "Our Own Apiary." I believe now that the best bees in the world are pure Italians, and that we shall have to continue to import them from Italy to keep them the best. W. W. WILSON.
Puerta Principe, Cuba, July 9, 1886.

"FOUNDATION JUST BOSS."

The queen came to hand in good shape. I introduced her at once, and she is now laying. The Peet cage is just the thing. That foundation I got of you is just "boss." I am well pleased.
Troy, W. Va., June 26, 1886. PERRY HANSFORD.

HOW THOSE GLASS HONEY-PAILS SUIT.

I am so well pleased with the little honey-pails, that my wife says she must have some more, as they are so nice to use for jelly as well as honey. The last goods received of you came on time, and in excellent shape. GEO. F. BRONDIGE.
Holly, Oakland Co., Mich., July 3, 1886.

THAT IMPORTED QUEEN.

Thanks for your promptness in sending me the imported queen. The order was sent June 24, and the queen was received on the evening of the 26th. I introduced her successfully; and on Monday morning, at the first examination, I found her not in the least bashful, but settled right down to business. I now have cells under way for queens.
Ashley, O., July 1, 1886. ELIAS COLE.

KIND WORDS OF SYMPATHY FROM HAYHURST.

Dear Bro. Root:—GLEANINGS for Aug. 1st is just received. I regret very greatly to learn from it of the trouble in your apiary; it most certainly is a great calamity. I have no doubt, however, that you will soon clean up your yard. Your manly courage in applying the heroic treatment is to be especially admired. E. M. HAYHURST.
Kansas City, Mo., Aug. 2, 1886.

THOSE CHAFF HIVES.

The ten chaff hives that you shipped me July 29th are received, and I have them nailed up and painted one coat, and I can say truthfully that it was as nice a lot of material as I ever had the pleasure of nailing together. I should like to have as many more, but will have to get along with what I have, as my honey-crop was rather short—only about 800 lbs. from 25 hives, spring count; increased to 37. D. J. SPENCER,
Hartford, Ohio, Aug. 9, 1886.

I received the basket of smokers, saws, mandrel, and files, in good order. I am very much pleased with them. The saws run very easily and work nicely. ALMON TOWER.
Lincoln, Neb., June 21, 1886.

THOSE NICE SECTIONS WE MAKE.

Those were the nicest sections you sent me that I ever saw. It puzzles me to know how you cut them so smooth. The Simplicities take the lead as far as I have seen. My bees are doing splendidly this season. I wintered 20 stands in Simplicity hives, outdoors, without the loss of one, which I thought good luck, not good management, for they had it all their own way. W. M. WILSON.
Huron, Kansas.

HOW OUR VEILS ARE GIVING SATISFACTION.

Brussels netting is the best, for the meshes are nearly round, hence are not so injurious to the sight, and it is but very little obstruction to the sight. I have hurt my eyes by using the common veiling. I think you should call special attention to it in one of your editorial notes; and if there is any thing yet still better, let us have it, at almost any price, and I think you would be doing service to the afflicted, and save many from affliction.
E. B. MORGAN.
Cleveland, Lucas Co., Ia., July 8, 1886.

I saw on the wrapper of my last GLEANINGS, that my subscription has expired, and also wished to know whether it gave satisfaction or not; and in reply I can say with a truth that I heartily indorse it, and also the manner you do buisness, so far as I am acquainted with it. I have dealt with you for the past three years, more or less, and in every transaction you gave entire satisfaction. I am one of Delos Staples' subjects to the tune of one dollar, but I don't ask you to pay me for his rascality.
G. W. CRETORS.
Cutler, Carroll Co., Ind., June 28, 1886.

I received my last copy of GLEANINGS last week, with a wrapper as usual, with extra printing on the outside, stating that my subscription expired this month. That is correct. Many thanks for your promptness in thus notifying us; and I must say that I for one have been privileged for one whole year to read a journal so full of interesting and useful instruction, and so free from slang and corruption. I am 43 years old, and this is my third year with bees. I love to work among them.
LEVI HILDEBRAND.
Hancock, Pottawattamie Co., Ia., June 26, 1886.

HOW TO MAKE THE QUEEN LAY DRONE-EGGS.

The queen you sent me came in good shape, and is a good layer; but she would not lay me any drone-eggs, so I put black brood in her hive until she thought (I think) she would have to swarm, and then she commenced laying in drone-cells; then I took the black brood away from her. I keep her colony rather light in numbers, for I do not wish her to swarm. I was pleased with my 15-cent vise. It was just what I wanted.
Mineral Point, Mo., June 28, 1886. O. F. BEAL.

HOW GOOD IT IS.

I received the A B C book all right. It is a beautiful book, inside and out. After I have read and studied it I will say how good it is. I am just a beginner in bee-keeping. When I understand better what I want I shall need many of your implements in bee culture. I started with one colony this last spring. The 1st of June a swarm came out and clustered in two places. We had provided only one extra hive, so we hived the small bunch in a nail-keg and the large bunch in the hive. The queen was with the small bunch. The others went back, and in two days came out again. I rehived them, and they went to work. Then I thought I need not watch for a time. So next day, out came another large swarm. I then resorted to another nail-keg. Too bad, isn't it? I could not get any hives made sooner than now, and they will cost $2.50 each. White clover began to appear in this section three years ago, and now some pastures are white with it.
FLORA K. SMITH.
Griswold, Cass Co., Ia., July 8, 1886.

HONEY COLUMN.

CITY MARKETS.

St. Louis.—*Honey.*—Honey moves remarkably slow. Choice white-clover honey, in sections, 1 ℔., salable at 10c, but holding for 11@12, as to size of lots. Good fair comb, in irregular packages, 8@9c. Extracted, white clover, in tin cans, held at 7c; salable at 5@6. In bbls., slow at 4@4½; kegs 4½@5. Dark strained honey, in bbls., 3@3½, for manufacturing purposes. *Beeswax.*—Selected, 25c. Mixed, as it runs, 22@22½c.

Aug. 23, 1886. Westcott & Hall,
108 and 110 Market Street, St. Louis, Mo.

Chicago.—*Honey.*—Demand for honey continues to be light, even at the low prices prevailing here—12@13c for best grades of one-pound sections. The offerings in houses who never received a case of honey until this season are large; and as they have not an established trade they are cutting prices. Extracted, unchanged.

Aug. 21, 1886. R. A. Burnett,
161 So. Water St., Chicago, Ill.

Kansas City.—*Honey.*—The market is active, and sale of comb is large. Extracted is firm, with no stock in the city. We quote to-day: White clover, 1-℔. sections, 13@14; same in 2 ℔. sections, 11@12; dark, 1-℔. sections, 11@12; same in 2-℔. sections, 8@10; California white sage, 2-℔. sections, 10@11; California dark, 2-℔. sections, 8@9. Extracted, white clover, 7@8; dark, 4½@5½; California white sage, 5½@6; dark, 4½@5. *Beeswax*, 20@22.

Aug. 23, 1886. Clemons, Cloon & Co.,
Cor. 4th and Walnut St's., Kansas City, Mo.

Cleveland.—*Honey.*—The market is unchanged since our last report. Best 1-℔. sections of white sell slowly at 14c; 2-℔s. slow at 12@13. Old honey not wanted at 10@11. Extracted, 6@7. *Beeswax*, 25.

Aug. 21, 1886. A. C. Kendel,
115 Ontario St., Cleveland, Ohio.

Detroit.—*Honey.*—The market for comb honey is very good, and a good many sales have been made. Best white in 1-℔. sections, 14c. *Beeswax*, firm at 23c. M. H. Hunt,
Aug. 23, 1886. Bell Branch, Mich.

Boston.—*Honey.*—We have had a small lot of new honey, and it sold from 14@16c, with good demand.
Aug. 23, 1886. Blake & Ripley,
57 Chatham St., Boston, Mass.

For Sale.—3000 lbs. superior white-clover and basswood honey in 1-lb. sections, delivered aboard cars at Dixon, for 12c in 24 or 48 lb. crates. 17-18
W. H. Swigart, Dixon, Ill.

For Sale.—3000 lbs. extracted honey, in 10-gallon kegs; 115 lbs. net; 7c for white clover; 6½ cents for raspberry. M. Isbell, Norwich, N. Y.

For Sale.—5000 lbs. of choice white honey—½ each of comb and extracted. The comb is in 4¼×4¼-inch sections, incased in neat crates (which are new) with two glass sides—14 sections to the crate. Price 14c per lb. Extracted is A No. 1, put up in new 10 and 17 gallon pine kegs. Above is all in first-class condition in every respect, and ready to ship on receipt of orders. O. H. Townsend,
Alamo, Kal. Co., Mich.

For Sale.—1000 lbs. white-clover honey, in 1-lb. sections, put on board cars here in nice glassed shipping-cases, for 15c per lb.; or if crates are returned free, 14c per lb. Herbert G. Green,
Emerson, Mills Co., Iowa.

For Sale.—500 lbs. white-clover honey in 1-lb. sections, 48 secs. in a case, delivered on board cars here for 15c per lb., cases to be returned.
Geo. P. Kime, Evansburgh, Coshocton Co., Ohio.

Wanted.—About 200 lbs. of white-clover comb honey, and 500 lbs. of white-clover extracted honey; comb honey to be in single-tier crates holding 25 4¼ sections, and weighing not less than 24 lbs. net. Extracted, in double cans crated in box, such as Root sells. Send samples and state lowest cash price. G. Wiederhold, Yonkers, N. Y.

For Sale.—California white-sage honey, 12000 lbs.; amber-colored, 2000 lbs. Sample on application. What am I offered on board cars at Los Angeles?
Geo. B. Woodberry, Verdugo, Cal.

For Sale.—1500 lbs. comb honey in 1½-lb. sec.; 1200 lbs. white clover at 12c.; and 300 dark at 10c., laid down here. John Crombie, Columbus, Wis.

For Sale.—I have about 800 lbs. of extracted honey, clover, put up in tin cans of 64 lbs. each. I will take 8c per lb., can included, delivered on board cars at La Grange. B. B. Wesley,
La Grange, Lorain Co., Ohio.

For Sale.—About 1200 lbs. of very choice white-clover honey, delivered on board cars at 13c per lb.; crates holding 36 sections each, all 1-lb. sections; crates thrown in. A. F. Unterkircher,
Manchester, Mich.

For Sale.—4500 lbs. choice white comb honey in 4¼×4¼ sections in new, bright, 24-lb. shipping-cases, glass fronts; 12c per lb., delivered at depot at Charles City, Iowa. C. A. Sayre,
Sargent, Floyd Co., Iowa.

For Sale.—3000 lbs. choice white comb honey in fancy crates at 11c; also 7000 lbs. extracted clover and basswood, very thick, in tin cans of 175 lbs. each, at 7c; placed on cars in any quantity on receipt of price. Oliver Foster, Mt. Vernon, Ia.

Wanted.—Extracted basswood honey.
J. G. Lehde, Gardenville, Erie Co., N. Y.

Wanted.—I will pay 13c per lb. for 100 lbs. of nice comb honey in 1-lb. sections, put up in 24-lb. shipping-cases, delivered at Ridgefield, Conn.
W. S. Gilbert, Ridgefield, Conn.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

Black and hybrid queens for sale now. Can ship upon receipt of order, and will guarantee safe arrival. Prices, black, 20 cts.; hybrid, 35 cts.
16-17-18 J. A. Bucklew, Clarks, Coshocton Co., O.

For sale, after Sept. 1, about a dozen black queens at 20c each, postpaid, some of which have mated with Italian drones. The above will be disposed of before the middle of the month.
R. Kilbourne, Jr., Clinton, Oneida Co., N. Y.

Six hybrids, at 25 cts. each; three are clipped.
C. G. Fenn, Washington, Conn.

I have a few mismated Italian queens to dispose of at 35 cts. each, or 3 for $1.00. These queens are almost pure. Geo. W. Beckham,
Pleasant Hill, Lan. Co., S. C.

I have 6 hybrid queens for sale at the usual prices. Geo. D. Raudenbush,
445 Chestnut St., Reading, Pa.

I have 15 black queens for sale at 20 cts. each.
R. B. Bonear, Cherry Ridge, Wayne Co., Pa.

I shall have some 12 or 15 hybrid and black queens on hand during August that I will take 30 cts. each for, or 2 for 50 cts.; or if there is any one not really able to give that, and wants one, send me a cage with stamp and your address, and I will *give* you one; or I will give one as a premium to those who never took Gleanings who will send A. I. Root a dollar for Gleanings for one year. These offers are good as long as I have any queens on hand, for they must be disposed of.
C. M. Hicks, Fairview, Md.

WE have for sale 6 very good tested Italian queens (1 hybrid) at $1.00 each, or $6.00 for the 7. Hybrids, 35c. Send $1.02 to return your money if queens are sold before your order comes.

CONVENTION NOTICES.

THE NORTH-AMERICAN BEE-KEEPERS' SOCIETY.

The society will hold its 17th annual convention, Oct. 12, 13, and 14, 1886, at Indianapolis, Ind.

The meeting will be held in Pfafflin's Music Hall, 82 and 84 North Pennsylvania St., one of the most pleasantly situated halls in the city. Good ventilation, and plenty of light.

The society headquarters will be at the Occidental Hotel, corner of Washington and Illinois Sts., in the heart of the city, and but a short distance from the hall. The regular rates at this hotel are $3.00 per day. Special rates for those in attendance at the convention will be $1.50 per day.

The North-Western Bee-Keepers' Society, The Indiana State, The Eastern Indiana, with various county and joint societies, will meet in union with the N. A., making it one of the most formidable meetings of bee-keepers ever held in this country. Every thing possible will be done to make the meeting pleasant and entertaining. A cordial invitation is extented to all.

The following is the programme:

FIRST DAY—TUESDAY.

Forenoon session, 10 A. M.—Convention called to order. Address of welcome by Gov. I. P. Gray. Response by the president, H. D. Cutting. Welcome to the city mayor, Caleb S. Denny. Thanks, Dr. C. C. Miller, president of the N. W. Society. Calling the roll of members of last year. Payment of annual dues. Reception of new members and distribution of badges, reports of secretary and treasurer. Announcements.

Afternoon session, 2 P. M., special business.—Annual address of the president; Bee Studies, by Prof. A. J. Cook, Agricultural College, Michigan; Apicultural Journalism, by John Aspinwall, Barrytown, N. Y.; Bee Literature, by Thomes G. Newman, Chicago, Ill.; The coming bee, what encouragement have we to work for her advent? by R. L. Taylor, Lapeer, Mich. Subject for discussion, Has Apis Americana been reached?

Evening session, 7:30 P. M.—Announcements. Miscellaneous business. Discussion of questions that may have accumulated during the day.

SECOND DAY—WEDNESDAY.

Morning session, 9 A. M.—Announcements. Communication. Call of N. W. Society to elect officers. Election of officers of Indiana State Society. Call to order, Rendering Comb into Beeswax, by C. P. Dadant, Hamilton, Ill.; Foul Brood, by A. J. King, New York. Selection of place for holding meeting in 1887. Election of officers.

Afternoon Session, 2 P. M.—Announcements. Miscellaneous business; Bee-keeping and Apiculture, by Prof. N. W. McLain, U. S. Apicultural Station, Aurora; Feeding Bees for Winter, by Jas. McNeill, Hudson, N. Y.; Wintering, by Dr. A. B. Mason, Wagon Works, Ohio; Subjects for discussion, Is the use of foundation necessary in modern bee culture? Are perforated honey-boares a success? Unassigned papers.

Evening session, 7:30 P. M.—Announcements. Miscellaneous business. Discussion of questions in question-box. Social communications.

THIRD DAY—THURSDAY.

Morning session, 9 A. M.—Announcements. Miscellaneous business. Communications. A Talk on Hives, by James Heddon, Dowagiac, Mich.; Reversible Hives and Frames, by J. E. Pond, Jr., North Attleboro, Mass.; Drones and Drone Comb, by W. Z. Hutchinson, Rogersville, Mich.; Reports of vice-presidents; Progress of Bee-keeping in Indiana, by Jonas Scholl, Lyons Station, Ind.

Afternoon session, 2 P. M.—Announcements. Miscellaneous business. Explanation of various articles on exhibition.

Many good things are yet to be added to the programme not sufficiently developed to give. **FRANK L. DOUGHERTY.**

The 4th annual meeting of the Progressive Bee-Keepers' Association will be held in the Town Hall at Bainbridge Center, O., on Thursday, Oct. 7, 1886. Parties wishing conveyance from Geauga-Lake Station, 3 miles distant, on the N. Y., P. & O. R. R., will please notify me so that arrangements can be made for the same. All interested are invited to come and bring their lunch-basket. **MISS DEMA BENNETT, Sec**
Bedford, Cuyahoga Co., O.

The Sheboygan Co. Bee-Keepers' Association will hold its next meeting at Chandler's Hall, at the village of Sheboygan Falls, on Saturday, Oct. 16, at 10 A. M. **MRS. H. HILLS.**
Sheboygan Falls, Wis.

The Southern Ill. Bee-Keepers' Association will hold its next meeting at Benton, Franklin Co., Ill., Thursday, Oct. 21, 1886, at 10 A. M. **F. H. KENNEDY, Sec.**

The annual meeting of the Western Bee-keepers' Association will be held in Pythian Hall, corner of Main and 11th Streets, Kansas City, Mo., Oct. 27, 28, 29, 1886. **P. BALDWIN, Sec.**

The Illinois Central Bee-keepers' Association will hold its next meeting at Mt. Sterling, Ill., on Tuesday and Wednesday, Oct. 19 and 20. **J. M. HAMBAUGH, Sec.**

KIND WORDS FROM OUR CUSTOMERS.

I am glad to inform you that the tested Italian queens bought of you in July last have proved to be all that I could have expected. I have produced very fine three-banded workers.
Emmettsville, Ind. **JACOB CAYLOR.**

The untested queen received from you some time since proves to be a fine one, and very fertile. She produces fine 3-banded workers. The season is very poor in this section. Basswood has failed entirely. Clover yield was not large. Buckwheat promises well, but is not fully out yet. **R. G. KLING.**
Charleston Four Corners, N. Y.

HOW TO PUT ON THE ROUND LABELS.

The goods came to hand. Those round labels No. 17 are beauties, and the place to stick them is on the inside of the glass (I use them for comb honey), just so they will be in the center of the section. They make very nice combinations and they will never get soiled, and the commission men can't get them off nor scratch off the address. **H. W. FUNK.**
Bloomington, Ill., Sept. 4, 1886.

The imported queen you sent to replace the missing one arrived safely, and is now laying in a new colony. We are well pleased with her appearance, and she seems to be especially prolific. And we are also much pleased with the way you settled the matter in regard to the loss of the first queen. We can not say that we expected you to replace her at your own entire expense, but felt willing to leave the matter entirely in your hands, feeling satisfied that you would do the fair thing in the matter.
Pomeroy, O. **S. A. DYKE & CO.**

I can not send off my order without expressing briefly my gratitude for such a blessing as GLEANINGS is to us. Each year I have taken it contains at least 24 happy days—the days on which GLEANINGS comes; and whenever I write to distant friends I tell them of its merits. I have kept bees now just nine years, and I am quite sure that no one ever cared more for their bees than I do. I am ever so sorry to know that you have foul brood in your apiary; but I like the method you have taken for a cure—the furnace idea. **W. S. POUDER.**
Groesbeck, Ham. Co., O., Sept. 2, 1886.

ITALIAN QUEENS, tested, $1.00; hybrid, 3 for $1.00. N. ADAMS,
18-19-20d Sorrento, Orange Co., Florida.

GOODS NEAR YOUR HOME, AT A REDUCTION FROM REGULAR PRICE.

We have the following lot of goods at the places named, for which we want customers. Now, it is altogether likely that there is some one located not very far from where these goods are who will be needing just such articles, especially if he can get them a little lower than the regular price, and doesn't have to pay much freight charges on them. In hopes that there are such persons, we append a list of the articles for sale, giving the present value of the goods and the amount we will take for each lot entire. We give a number to each lot, and the name of the place where they are being held, subject to our order. Remember they are all perfect goods, just as fresh and new as if shipped from here. Remember, also, that at the price we offer them we can not break lots; each lot must go entire. In making your orders, please give the number of the lot as well as the articles contained in it, and thus help us to avoid mistakes.

No. 1. Aplington, Iowa.

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey.*—The season for the new crop of comb honey is just opening. We note an improvement in sales and prices. Most of the comb which we have seen is badly colored, which makes it second grade, which we suppose is due to a poor season and long finishing. We quote 1886 crop as follows:

Fancy white 1-lb. sect's, clean and neat p'k'gs.	15@16
“ “ 2 “ “ “ “ “ “	12@13
Fair to good 1 “ “ “ - - - - -	12@14
“ “ “ 2 “ “ “ - - - -	10@11
Fancy Buckwheat 1-lb. sections, clean - -	11@12
“ “ 2 “ “ “ - -	9@10
White Clover, extracted, kegs and small bbls.,	6½@7
California extracted, 60-lb. cans, per pound,	5@5½
California Comb - - - - - - -	10@11
Beeswax, prime yellow - - - - - -	22@24

McCAUL & HILDRETH BROS.,
Sept. 2, 1886. 34 Hudson St., Cor. Duane St.

CINCINNATI.—*Honey.*—The market for honey is very tame. Demand from manufacturers is slow, and there is only a fair trade in new comb honey, and extracted honey in square glass jars. Extracted honey brings 3½@7c. per lb. on arrival. Comb honey brings 12@14 for good to choice in the jobbing way. Prices are low for all produce, and no speculative feeling is noticed anywhere. Unless better prices are realized for other produce, prices of honey are not likely to advance. *Beeswax* is in good demand, and arrivals are fair. We pay 20c. per lb. for good yellow. CHAS. F. MUTH & SON,
Sept. 2, 1886. S. E. cor. Freeman and Central ave.

KANSAS CITY.—*Honey.*—Extracted is arriving more freely. Extracted white clover, 6½ @ 7½. Other grades the same.
Sept. 10, 1886. CLEMONS, CLOON & CO.,
Cor. 4th and Walnut St's, Kansas City, Mo.

DETROIT.—*Honey.*—No change in the honey market since last quotations. There is sufficient in the commission houses to supply the demand. Best white in 1-pound sections, 14 cts. *Beeswax*, 23 cts.
M. H. HUNT, Bell Branch, Mich.
Sept. 10, 1886.

BOSTON.—*Honey.*—New honey is coming in, and selling fairly well, but the recent hot wave has checked it some. We have heard from most of the bee-keepers of Addison Co., Vt., and there will not be over half a crop there. We are selling one-pound white honey at 14@15c.; two pounds, 13@14.
Sept. 10, 1886. BLAKE & RIPLEY,
57 Chatham St., Boston, Mass.

CHICAGO.—*Honey.*—Honey is without change from last quotations. Weather continues warm.
Sept. 10, 1886. R. A. BURNETT,
161 So. Water St., Chicago, Ill.

MILWAUKEE.—*Honey.*—Market remains about the same as when last reported; may be quoted little lower to sell.

Choice white comb, 1-pound sections - -	12@13
“ “ “ 2 “ “ - -	11@12
Extracted white, in kegs - - - - - -	6@6½
“ “ “ tin - - - - - -	6½@7
“ dark “ barrels - - - - -	5@5½

Beeswax, no demand. A. V. BISHOP,
Sept. 10, 1886. 142 W. Water St.

ST. LOUIS.—*Honey.*—Comb honey is in good demand for choice white-clover in sections, 1-lb., 12@12½; other varieties, 10@11½. Extracted honey very dull; cans, 5@7 for choice in a small way. On large lots, 5@5½ are as much as would bring. Old honey in cans 4@5c. Southern honey in bbls., good to choice, 3½@4; extra, 4½c. *Beeswax*, mixed lots, 22c.; selected yellow, 25c. WESTCOTT & HALL,
Sept. 10, 1886. 108 and 110 Market Street.

CHEAP HONEY.—I have about 350 lbs. of honey in nice 22-gallon kegs. It is dark, but very thick, and is splendid bee-feed, or good for factory-men. I have to move soon, and must sell it. You may have it for 3 cts. per pound, by the keg of 250 lbs., at depot here. M. J. HARRIS,
Clay City, Clay Co., Ill.

FOR SALE.—7000 lbs. extracted honey of the best quality, part pure white clover, part white clover slightly mixed with basswood, put up in new oak paraffined barrels holding about 500 lbs., at 7c. per pound, delivered on cars here, packages free.
RUFUS PORTER, Lewistown, Ill.

WANTED.—I want 100 lbs. of white extracted honey. What will you charge me for it, laid down at my depot at Rogersville, Mo.? I may want more.
S. S. LAWING, Henderson, Mo.

Ten bbls. of nice thick honey, 52 gallons each, for $35.00 per bbl., delivered on board boat at Gaines' Landing, Ark. Sample sent free on application.
W. G. McLENDON, Gaines' Landing, Ark.

A FEW VALUABLE SUGGESTIONS FROM J. A. GREEN.

SOLAR WAX-EXTRACTORS.

IN the extractor I sent you, I left off one important feature in order to make an extractor more easily shipped and less easily broken. This was the "side reflector." This is an important adjunct, and this season's use has convinced me that I would not want to do without it.

To make it, take a thin board, or combination of boards about four inches shorter, and an inch narrower (or vice versa), than the inside of the cover. Cover one side with tin, and on the other side put a cleat in the middle, or one at each end, projecting three inches on one side. Now nail a "pocket," or small box, on each side of the extractor, blocking it away from the side so that the sash can be raised without interfering with the reflector. The reflector is to be placed on the west side in the morning, and changed over to the east side at noon. At night it is laid on the sash, and the cover closed down over it.

Of course, this side reflector is not of much use if the extractor is kept facing the sun all the time; but a busy man can not well do this.

In making beeswax in times past, I have been much troubled with "spongy beeswax," a sort of combination of wax and water that would sometimes be two or three inches thick on the bottom of cakes of wax. It seemed to be caused by boiling, or, at least, too much heating, in combination with water. Sometimes the wax would be granular, as I believe you have mentioned. In both these cases the wax seemed good enough, only it appeared to have got tired of assuming the old forms. I find that I can make such wax "behave" by running it through the solar extractor. I have also succeeded in getting a considerable quantity of good wax from the scrapings of wax cakes that I had formerly supposed entirely worthless. "Keep it before the people," that the solar wax-extractor affords the best and most convenient way of making beeswax yet invented.

Speaking of extractors reminds me that I have never made any report on the rim you sent me for the top of my honey-extractor. I have just been extracting some very thick honey, which has afforded a good test for it. It does not entirely prevent the flying over the top of the can when the honey is very thick or not very warm; but under ordinary circumstances it does away entirely with this very annoying feature.

SMOKER FUEL.

I have used planer shavings in the Clark smoker very successfully. In the spring, and fall too, I have used with great satisfaction a fuel that I have never seen mentioned by any one else. This consists of the dry leaves of the soft maple. These are very soft and fine, and I use them largely for packing hives. Being always handy, it is very convenient to use them as fuel. With a little care they answer the purpose excellently, and last much longer than one would suppose who had never used them. To keep such light fuel from going out in the Clark smoker, it is necessary to use an admixture of something more solid. When using leaves, I start the fire with rotten wood and then use alternate fillings of leaves and wood. When using shavings in the Clark smoker I mix them half and half with good rotten wood. This mixture burns well, and holds fire well, although it does not do as well as the shavings alone in the "Doctor." W. Z. Hutchinson, in telling how to light the smoker, just misses a convenience which I would not think of doing without. This is the use of kerosene in kindling the fire in smokers. Have a zinc oiler full of kerosene, handy to the place where you light your smoker, and squirt a little of it on that handful of shavings; light your match, drop it in—no need to "carefully set it on end"—and puff away. If you have no oil-can, use a small bottle with a quill through the cork. A very little oil is enough.

Mr. Heddon tells us to use wet shavings as a spark-arrester. Instead of these I prefer to use a handful of stiff wiry grass or weeds—not too coarse nor too succulent, coiled in the cap of the smoker. Knot-grass is best. This coil of weeds completely prevents the throwing of sparks, and you can tell by the smell when your smoker needs filling. I used to try to get along with as little smoke as possible. Now, I want a smoker that will throw smoke enough in two or three puffs to take the fight out of the worst hybrids. If the bees are willing to be handled without smoke, all right; but if they show fight I make them behave, and waste no time about it. A good smoker is one of the best time-savers a bee-keeper can use, to say nothing of the extra comfort over a poor one.

Dayton, Ill., Sept. 10, 1886. J. A. GREEN.

Thanks, friend Green, for the improvement you suggest for the solar wax-extractors. We have found the granulated wax a very serious trouble, and we have never succeeded in doing any thing with it except by mixing it with a considerable quantity of good wax, and stirring it until it behaves itself, as you express it. If the solar wax-extractor will restore it, it is indeed a great fact.—No doubt your suggestion of dry leaves for fuel for smokers is a good one: but, my dear sir, the idea of filling a small oil-can with kerosene, for kindling fires of any kind, it seems to me, is something of wonderful value. Why, you can give the hired girl, or the cook, even if the latter be fresh from foreign shores, such an arrangement to light her fires with, and she *can't* do any harm. Why has no one ever thought of it before? Our five or ten cent oilers will do it exactly. On some accounts I should prefer the five-cent one, because the quantity of oil would not be sufficient to set any thing afire, if left on the stove, or dropped into the stove. Your idea of stiff wiry grass for a spark-arrester is also a valuable suggestion. See Our Own Apiary, this issue.

INTRODUCING QUEENS.

A DRONE-TRAP NEARLY EQUAL TO ALLEY'S.

I HAVE had quite a time introducing queens. I have introduced four the past month. One of these the colony rejected five times. I then formed a nucleus of young bees, and they took her without a moment's parleying. Another one was refused by another colony four times, whereupon I introduced her to the colony that had so cordially rejected the first-mentioned queen, and all was as peaceful as a summer morning, and I was relieved, for she was a fine one. The instructions for introducing accompanying Peet's cage would be quite incomplete were it not for your added note. Had I not followed it I should have lost, no doubt; for at the expiration of 2 days I found her balled, and a more persistent cluster I never had to dissolve. I deluged them with tobacco smoke, and finally had to rake them apart with a twig, and then they seemed loth to yield. I have found Alley's plan as successful as any. The queen to be superseded is removed from the colony; when the bees are back and quieted, the cage containing the new queen is placed on the combs under the mat, in such away that the bees may have access to the food. Then a small amount of tobacco is blown into the hive, thus scenting the bees and queen alike. In the course of two hours he says (though not in a single instance have mine been liberated under 24, and I used his prepared cage), the queen is released; and as the colony has not had time to miss their old queen, the new one is successfully introduced. I would add, that where there is delay in her release, as has been true in my case, an hour or two before she emerges I would fumigate them again, as the first smoking will have entirely lost its virtue. Of course, a portion of the food could be removed, and a more speedy release effected. Last year all my queens were purely mated. This year there is a new comer, a few blocks away, who keeps blacks, and in almost every case this year the queens have been impurely mated. He has but a few colonies, and I purpose queening them for him with pure Italians. I think this would obviate the difficulty.

And now about my drone-trap. It is hardly equal to Alley's, but good, nevertheless. It is in the shape of a brood of quarter-grown Leghorns. I noticed they frequented the bee-yard, and my suspicion was aroused, so I watched them. I was soon struck with dismay at seeing them pluck up bee after bee with a dexterity that was surprising. I disliked to dispose of them, for they were fine ones, well marked. The thought struck me, "Perhaps they are taking only the drones," for I noticed they received no stings, and, sure enough, after long and close watching I found they did not molest, or even notice the workers; so in place of a pest I had a prize. How remarkable! and none but the Leghorns would be up to it. It seemed strange that they had learned so readily to distinguish between the "lancers" and the civilians; and now a question: Can a chicken swallow worker-bees without imperiling its life? I have heard that they do; but is such a thing positively known?

GLEANINGS grows in favor with me. It is second to none. FRANK C. BLOUNT.

Lawndale, Ill., Aug. 19, 1886.

Friend B., if I am not mistaken, common fowls may learn to catch and kill worker-bees; at least, such facts have been furnished, supposing they were worker-bees. As many of the feathered tribes catch and kill worker-bees when the bees are gorged with honey, why may not common fowls? My idea has been, that the fowls mash the bees with their bills until the bees are unable to sting. Of course, it requires pretty thorough mashing to prevent the sting from working of itself, after the bee is dead. If, however, it should be proven that it is only *drones* they take, we can well afford to encourage fowls about the apiary.

FOUL BROOD.

SOME BOLD SUGGESTIONS IN REGARD TO ITS CAUSE AND CURE.

MR. EDITOR:—You so frequently receive communications suggesting such wild ideas and new ideas—which are not new—that it is very probable you will regard what I have to say as simply an addition to the wild ideas before mentioned. This subject, foul brood, is, without a doubt, the greatest bugaboo to the bee-keeping fraternity; but when bee-keepers become thoroughly aware of its nature, and the causes which bring it on, then will it dwindle into insignificance, and will be of less importance to the bee-keeper than the marketing of his honey.

Last year I had the disease among my bees in its very worst form. I could smell the odor given off by the hives, thirty yards from the apiary. I tried both phenol and the starvation method of cure; but it seemed the more I did for them, the worse they got. I tried the phenol cure until I had used 2 lbs. with a very discouraging result. I tried the starvation plan on thirty, but did not cure any—except two that I starved to death.

While I was trying to cure some by the remedies above mentioned, a period of about ten weeks, I not only kept a record of those which I tried to cure, but of those that I did nothing for. Any one who has read a great deal on the subject can judge of my perplexity when I discovered that the colonies affected that I did nothing for were in a better condition than those I doctored. Since I made the discovery above mentioned, I have had a new idea as to the nature of the disease. This idea has been so confirmed by what I have read, and by later experience, that I am now confident I can state some new and valuable facts on the subject.

Foul brood is caused, chiefly, by an inferior quality of honey or honey-dew; but it is sometimes caused by physical defects in the queen, from which the larvæ inherit a constitutional weakness. The former kind, or class, I should say, breaks out in several colonies, and sometimes every colony in an apiary at once (which accounts for Mr. D. A. Jones's belief in spontaneous generation). Of the latter class, you will find only one or two in an apiary at one time. It is cured by simply replacing the queen. When the disease is caused from bad honey, the best thing to do, in nineteen cases out of twenty, is to let it alone. But if you want to cure it, take the honey from them, boil it, and give it back; or, better still, give them nice honey from flowers, or sugar syrup.

Some might say that I ignore the fact that learned scientists have traced the cause of the disease to bacteria; but I do not. We all know, who read the bee-papers, that the disease is accompanied by bacteria; but who can say that bacteria is the prime cause of the disease? No one. To say that it would give a hardy frontiersman the consumption if he were inoculated with the bacteria that accompanies that disease, would be about as reasonable as to say that one spore from the foul-brood bacteria would affect a healthy larva.

Can any reader of GLEANINGS think of any hypothesis, outside of the facts I mention, with which the different methods of cure can be reconciled? D. A. Jones cures by after-feeding, and not by starvation. Frank Cheshire effects a cure by feeding and not by phenol. Those who think they cure the disease by thyme, camphor, or salt, simply let it get well itself. Then there is N. W. McLain's method—a sure one; and C. F. Muth's method, another sure one; either one of which would be sufficient without the medicine. I could fill a book with proof of the assertions I have made; but I have said enough now to raise the ire of a great many, who, once getting an idea in their head, can never get it out. However, I am going to hazard just one more, and here it is: When there is a good flow of honey from the flowers, you can not hurt a populous colony of bees if you were to give them ten combs of the most malignant type of foul brood, in addition, of course, to the combs they have already.

Mobile, Ala., Sept. 4, 1886. GEO. H. HOYLE.

Friend H., you almost startle me by your reasoning; and if you are not exactly on the right track, I feel sure you are pretty close to it. For years back, the conviction has again and again been forcing itself upon my mind that the remedies prescribed and used for different diseases of the human family, in a great majority of cases have nothing to do whatever with the recovery of the patient. Sometimes some trifling thing, in some remote way connected with the treatment, has been the cause of the cure, in a way something like what you suggest in regard to foul brood. Let us go slowly, and let us have much charity while we push our investigations. I believe it is one of the hopeful signs of the present age, that we are more and more using reason and common sense, and are discarding blind hits in the dark,—guessing that a certain medicine *may* hit the spot.—I know you are right in one of your propositions; namely, that something strikingly like foul brood may exist in the hive because of a physical defect in the queen; and that changing the queen furnishes the cure. We have had such cases in our own apiary; but when shown to me I have at once decided where the trouble was, and effected a complete cure by giving the colony a good queen.—In regard to the second case, that it is produced by some kind of honey that kills the brood at such a stage, it seems to me this may be partly true, but not always the trouble; for instance, how can it spread from one apiary to another by a purchase of stocks, old hives, or fixtures? Scalding the food, whatever it is, would probably prevent it from going further.—Right here I want to tell you some of the difficulties we met at this point in our apiary in stopping it after the plan we have been working on. We at first concluded it was unsafe to open the hive in the day time, because the robbers might slip in and carry off some of the infected honey; therefore we decided to use a tent. But our apiarist soon declared the tent was even worse than no tent, because bees, returning from the fields, on finding their hive covered with a tent, would, a great many of them, carry their loads of honey into the hives adjoining on all sides. This, I have known for many years, was true. It requires the utmost caution and care to prevent the disease from spreading to hives adjoining the infected one, and I begin to think, of late, that perhaps the only really safe way for a person of average skill and intelligence is to take the hive after dark, when every straggling bee is at home, and burn up all the bees, combs, and stores, unless, indeed, we adopt your plan, and let it die out of itself. But, my good friend, please consider that hundreds of bee-keepers have been already adopting this latter plan, and it did not "die out," either—no, indeed. It spread until it ruined not only every colony in that apiary, but, when robbers set in, almost every colony in adjoining apiaries, in spite of every thing the owners could do. By all means, let us have reason and common sense applied to the matter, but don't let us get reckless.

PROFIT IN BEES.

HOW TO COMPUTE IT.

ONE is apt to conclude, from a superficial observation without experience, that all the honey that can be secured from a number of hives is clear profit. If there were no work attached, and no investment necessary, this conclusion might be correct. While taking these into consideration we find that some years we are able to secure a much larger profit than others, while occasionally the bees prove an actual loss. In making up the amount of profit and loss we must keep an account, first, of the money invested in hives, bees, and such other necessary appliances as we find necessary. We must allow a per cent for interest on the money invested, as well as a sinking fund for the wear and tear. Then our time must be worth something. True, we may be able to do the greater part of the work at odd times, so that some often conclude that this should not be counted; but this time is certainly worth something. If we were not attending to the bees we could be doing something else, so that the only correct way is to charge the profit-and-loss account with whatever the time required is worth. If you are required to feed them at any time, this also should be charged for what it is actually worth. In this way we know what the honey we secure costs us. If a patch of buckwheat, clover, or other plant, is sown for the express purpose of feed, this also should be charged.

Whatever honey is taken, whether used in the family or sold in market, should be credited at whatever it is worth. If some of the bees are sold, this also should be credited. Any expense incurred should be charged; and whatever is received for any thing should be credited; and the difference between the two will show the amount of profit secured or loss sustained.

With good management, bees, of course, can be made profitable; but a little experience will soon convince any one that it is not all profit; while if properly managed, with any thing like a fair season, bees may be made to yield a very large profit on the money invested. N. J. SHEPHERD.

Eldon, Mo., Sept. 1, 1886.

POLLEN FROM COTTONWOOD-LEAVES.

ALSO MORE ABOUT OPEN-SIDE SECTIONS, AND NO SEPARATORS.

DEAR EDITOR AND GLEANERS:—For several days past I have heard during the forenoon a loud roaring of bees in a small cottonwood-tree near my apiary. I at first thought they were gathering honey-dew, as I have noticed a slight sprinkling of this substance in a few hives. Upon closer examination I found that they were scraping a yellow substance from the surface of the leaves, and packing it in their pollen-baskets. The leaves of this tree are almost yellow with this substance, while those of larger cottonwoods near by show no traces of it, and I saw no bees on them. There are, of course, no blossoms on the trees at this season. I inclose a few of the yellow-coated leaves. An explanation will be appreciated.

SECTIONS OPEN ON ALL SIDES.

On page 689, after speaking of my new open-side section, friend Greer says: "It seemed to be intended to be used without separators, and, in consequence, with sections both wide and narrow. I had bulged combs, so I have attempted to devise a separator that could used with open-end sections."

Friend G. seems to have overlooked the fact, as explained in my pamphlet, that, in the section referred to, special provision is made for the use of *ordinary* separators, which renders his improvement in separators unnecessary. The only difference is, that the slots all around are a little shorter and deeper. They are 3 inches long, and scant ¼ inch deep, which enables the bees to pass freely, not only on both sides of the separator from one section to the other, but also between the outside row of sections and the side of the case. The wide openings also seem to serve as a more perfect guide to the bees, causing them to build straighter combs, and with less bulging. In fact, after learning how to use these sections, I have abandoned all separators in my own apiaries, as I find I can secure as perfect combs with far less labor and expense than with separators. I find that sections half full of fdn. produce more perfect combs than filled ones. OLIVER FOSTER, 296—325.

Mt. Vernon, Linn Co., Ia., Sept. 7, 1886.

Friend F., the yellow substance which you find on the leaves, and which the bees are using as a substitute for pollen, is a sort of fungoid growth, similar to the reddish substance often found on the leaves of raspberries, and which the bees have repeatedly gathered as a substitute for pollen. It would seem from this and other similar reports that bees can use a wide range of animal and vegetable secretions in the way of pollen, or as a substitute for pollen from natural flowers. Our older readers will remember that our bees were at one time gathering dust from the shelves of a cheese-factory, and that this dust, under the microscope, proved to be microscopic forms of animal life.—If your arrangement will enable yourself and others to get nice comb honey without the use of separators, it is something of more moment than we at first supposed. We should be very glad to have further reports from you.

FOUL BROOD.

THE DESTRUCTION PLAN VERSUS THE OTHER REMEDIES.

AT the close of the honey season last year I discovered that every colony in my apiary was more or less affected with foul brood. I had never seen the disease, and, of course, had no knowledge of it except what I had obtained from reading, and what I had heard in the discussion of the subject at the National Bee-Keepers' Convention in Cincinnati, Oct., 1882. It seemed to be the prevailing opinion of the members of the convention, that the surest remedy for the disease is to kill the bees and burn the hives and combs. I admit, that Mr. Jones, who was present, said that he could cure it by the so-called "starvation plan;" and Mr. Muth also asserted his confidence in the efficacy of salicylic acid; but the destruction method seemed to be the most popular with the bee-keepers present. I accordingly followed the destruction plan, with the exception of two that were very strong in bees, and had not a very great extent of foul brood. I had not time to try the starvation plan, so I put them in the cellar, with the intention of trying it this summer, if they were alive in the spring. They wintered well. During the winter I heard of Cheshire's pamphlet on foul brood. After reading it I concluded to try his remedy, phenol, on my affected colonies, when I should set them out in the spring. Afterward I read in the *Bienen Zeitung*, a German bee-journal, that powdered brown coffee is a powerful antiseptic, and a destroyer of foul brood. I now had two remedies, phenol and coffee, and I determined to try phenol on one colony and powdered brown coffee on the other. Accordingly I gave phenolated syrup (1 part to 500 parts), with a feeder placed over the cluster, and covered with a cushion. I did it as soon as I set them out in April.

I applied the coffee finely ground, by removing the combs one at a time and taking the powdered coffee in my hand, sprinkling it over the combs, bees and all, and into the cells and all the crevices and cracks, and over the tops of the combs when replaced. I treated the colony in this manner three times, at intervals of about a week.

The colony treated with phenol took about half a gallon of the medicated syrup. The last of last month I examined both colonies, aided by my friend, an experienced bee-keeper, C. Spangenberg, of this city, who has had some experience with the disease, and we found not only no trace of the disease, but both were in a healthy and flourishing condition.

From these tests it seems that each remedy is equally efficacious. Coffee is to be found in every house, but phenol is not so easily obtained, and coffee can not possibly injure the honey or the bees. I think the bee-keeping world is to be congratulated in having so pleasant a remedy, so easily applied, and so efficacious. I hope all who have the disease will at once try coffee. Grind or powder it very fine. J. W. VANCE, M. D.

Madison, Wis., Aug. 23, 1886.

Friend V., before you read what I have to say in regard to the above, please remember that I have very little faith in remedies, unless I can see some consistent reason for applying such remedies. And now excuse me for saying that I can not believe your finely ground coffee had any effect whatever over the foul brood. The phenol may have had some effect—I do not know; but as a good many have reported that they could not see that it made any difference, excuse me for being somewhat skeptical in regard to phenol also. Do you ask, how, then, the disease came to disappear? I think it disappeared of its own accord. A friend has written us, that, in order to test a remedy for foul brood, he used it on a part of his colonies, and used nothing on the rest. After some time, on finding the disease had disappeared on the treated colonies, he was ready to shout eureka, but concluded to examine those not treated before doing so. To his astonishment he found the disease had disappeared from all—those treated, and those not treated. Now, a great many experiments are made like the one you note above. The disease is gone, it is true; but how can you be sure the coffee or phenol either had any thing to do with its disappearance? See also last paragraph of article from E. C. Long, on page 701, last issue.

BRUSHING BEES OFF THE COMBS, VERSUS SHAKING.

CONTRACTING BROOD-CHAMBERS NOT SUCCESSFUL WITH MRS. AXTELL.

IN last GLEANINGS it was remarked, it did not so anger bees to shake them off the combs as it did to brush them off. True, it does not; but is there not danger of injuring the brood to shake it too hard? We know that queens' wings may be thus injured, and why not worker-bees? I generally shake them enough to shake the clusters off, and then stand to one side, or, rather, corner, of the hive, generally the southeast corner, of hives facing the south. Hold the comb in the left hand, and, with a soft grass brush (never a feather brush, if grass or weeds can be had), brush the rest of the bees off, being careful not to stand in the bees' way, so they can not alight in front of hive. Getting in their way also angers them.

This spring we thought we would try small brood-nests after swarming, so as to get most of the honey in the surplus-cases, as some are advocating. We had tried it before, but thought we would try it again, as it is claimed we did get most of the honey in such hives in the surplus-cases; but those colonies did not equal those hives that had their full number of combs. Before the spring harvest had closed, those colonies were smaller, consequently they gathered less honey. If a colony gets run down in numbers in mid-summer, with us, it does not of itself build up in time for the fall crop, generally commencing the last of August. Mr. Axtell and I conclude that seven Quinby brood-frames are none too many for this locality, except in the winter and early spring; then four or five are better; but seven and eight full of sealed stores are none too many to bring them in the best of condition through winter and spring, taking away empty ones in the spring and giving full ones, or adding a full one if those in the hives are full of brood. In order to have large colonies ready for harvests (large colonies are the paying ones for comb honey), we need in this locality to keep them built up, according to our opinion. Different localities need different management, no doubt. **Mrs. L. C. Axtell.**

Roseville, Ill., Aug., 1886.

Thanks, Mrs. A. No doubt you are right in regard to the danger of contracting the brood-nest too much. We believe in large colonies, and I have never yet seen them too large, providing the bees were all the progeny of a single queen.

FLAT-BOTTOMED FOUNDATION VERSUS OTHER MAKES.

THE ECONOMY OF THE LATTER OVER THE FORMER, PROVEN BY CAREFUL EXPERIMENTS.

LAST season I used flat-bottomed foundation for surplus honey. The bees, in trying to turn the flat bottoms into the natural form, spoiled some and neglected others. Having seen that, I looked up what you say on page 56 of your A B C, and, consequently, I made up my mind to get a foundation-mill which I could use for foundation for brood-nest and for surplus honey, as I had suspected the purity of the wax of some foundation for brood-nest, which I had received from England. I ordered a machine with ten-inch rollers, from you; and when I received it, in January last, I bought some pure wax and tried to make foundation for brood-nest. My first trial failed, as the wax sheets were so hardened by the cold weather that they generally broke. I read over the instructions given in the A B C book, and decided on shutting the windows and doors, and to place a big fire in the room. This, however, made but little difference; and so after a while I thought of dipping the wax sheets in warm water, about 110° F., just before passing them through the rollers. I tried this plan and the result was perfectly satisfactory, so that the sheets came out from the rollers very easily, and the foundation was perfectly even and nice.

In the latter part of February I gave to each one of my eight strongest stocks of bees two full sheets of comb foundation, the one being of my own make, and the other of the lot I had received from England, I placed the one at one side, and the other at the other side in the brood-nest of each hive. About ten days after, on examining I found that the foundation I had made was all accepted by the bees, cells having been drawn out nicely, and filled in with eggs, etc., and that the foundation I had received from England was all sagged, and only the cells at the lower part were half worked out. These I left in the hives for about two months, and by so doing I have been able to ascertain that the bees had been obliged to use them by thickening the upper parts of the foundation with their own new wax in order to prevent the falling-down of the above-mentioned combs, of which only the lower parts were occupied, and the upper parts were out of shape.

In March last I bleached some pure wax in the manner explained on page 288 of the A B C book, of which I made some foundation for the section boxes just in the same manner as I had made those for the brood nest. This foundation was of medium thickness, and its color was as white as snow; and having still on hand about three pounds of the flat-bottomed foundation I fixed full sheets of both in the section boxes, and in April I supplied the bees with both kinds mixed together in the crates for perfect trial.

About a week after, on examining the same, I saw that some of the flat-bottomed foundation was untouched, and some, especially that in the center of the crates, was in a bad state, so that the bees, in trying to turn the bottoms into the natural shape, had partly spoiled them. While all those made by me were accepted, and their cells or walls were beautifully drawn out, which looked very pleasant to the eye, and the bottoms of the cells were so thinned out that I could hardly see any difference between mine and the natural comb, except that mine were less transparent, owing only to the air, or to the imperceptibly fine spaces created in the body of the wax by its swelling when dipped in warm water, which air, on account of the warm and soft state of the wax, did not escape by the pressure of the rollers of the machine, and it caused the wax to remain in such a condition that the bees would hardly find any difficulty in scratching the thick parts of the foundation and using the shavings for the building of the walls. When I was rolling, Mr. F. Benton was present, and he told me that I was going to have a fishbone in my surplus comb honey, and so I thought that would have been the case; but after it was worked out by the bees I was very glad to see the unexpectedly excellent results.

Herewith I send you samples of the flat bottomed, and also of my own make of foundation, as worked up by the bees, that, in the event of any progressive bee-keeper wishing to ascertain the truth of what I have stated, he may be able to see the results with his own eyes, and thus he will be better able to judge than by explaining the matter scientifically. I would also beg all bee-keepers who love progress to try my system of rolling the wax, and discuss the method for the benefit of all, by taking under their careful consideration the state or shape of the wax scales secreted by the bees, and the manner in which they are worked for the comb.

M. G. Dervishian.

Larnaca, Cyprus, August 10, 1886.

Friend D., your experiments have resulted just about the same as our own. The samples you send us are beautifully thinned at their bases; and I believe no one has yet tried to explain why bees sometimes scrape down the base so thin, and at other times do not. The specimens you send make it very plain indeed that extra labor is required where the bees have starters of flat-bottom foundation.

COLOR AND QUALITY OF QUEENS.

FRIEND DOOLITTLE'S EXPERIENCE IN TESTING THE DIFFERENT RACES.

CONTINUING the subject of my article on page 643 of Gleanings for Aug. 15th, we have next in order the color of the queens of the different races of bees. The queen-bee of the German race seems to be the most constant in color of any of the bees which have come under my notice, all of which are of a very dark brown upon the upper side of the abdomen, while the under side of the same is of a yellowish brown. Right here I would say, that, in speaking of markings, I shall notice only those which are fixed, or permanant, as are those colors on the horny scales, or segments of the abdomen; for nearly all other markings are of hair or fuzz, and are soon worn off, so that an old bee does not look nearly as showy as a young one, when the color of said fuzz is new and bright. The head and thorax of all the races of bees are very much alike, except as the color of this fuzz gives them a lighter or darker appearance. To be sure, the Cyprians have a bright spot, or shield, as it is called, at the back of the thorax between the wings; but as I find this same spot on the best-marked Syrian and Italians, I do not see how it can be used as a test for purity of the Cyprian race, as some claim for it. Hence the abdomen of the bee is the place we are to look for the markings of the different races. With me, the markings of the Cyprian and Syrian queens are very much alike, except that the strips or rings on the Cyprian queen have more yellow on them than do the Syrians; and said yellow is of a bright orange color, while that on the Syrians is less bright, and often dusky. Every segment to the abdomen has both yellow and black upon it, unless it be the last one at the tip, which generally is nearly or quite all black, or very dark brown. The queens to these two races of bees are next in constancy of color to the German queens. The few Carniolan queens which I have reared run from a jet black to a light brown, one of which was fairly a blue-black, like a crow, or a crow blackbird, as we call them here. However, I did not keep this variety of bees long enough to give a decided opinion of the color of either bees or queen.

We next come to the Italians; and, without wishing to injure anybody's feelings or business, I am compelled to say that I can consider them as only a hybrid or mongrel race. There is no constancy of color, either in the queens or bees. Furthermore, I believe that it is this mongrel quality which gives them their good qualities as honey-gatherers. Surely no race of bees can be said to be *pure* whose queens vary in color from that of a German queen to a bright golden-orange color the whole length of the abdomen, some of the best specimens not even having a particle of black on the extreme tip, or point. Again, the workers vary from a dark chestnut color, so nearly like the German bees that only an expert can tell the difference, to those showing the fourth and a few even the fifth band of golden yellow. I used to think that queens of the Italian variety could be found that would duplicate themselves; but I have long ago given that up. However, the queen which I prefer for a breeder is one which will give the larger share of her young queens of a bright orange color. Such queens, mated with drones from a like mother as to markings, though in no way related as to blood, give me the best results in honey of any bees I have ever tried. In fact, I believe they have no equal as honey-gatherers; and with our present mode of management, together with comb foundation in our sections, they are all I could desire as comb-builders. I again repeat what I said in the A B C, several years ago, that $500 would not tempt me to exchange my present stock of home-bred Italians for those imported, or for any other bee which I am acquainted with.

QUALITY OF QUEENS.

Next comes quality of queens reared by natural swarming as compared with those reared "artificially" at it is termed. All, without doubt, know that I prefer queens reared under the swarming impulse; and about the only reason I can give for such a preference is, that such queens prove, on an average, to be of one-third more value to me than do those not so reared, with the exception of such queens as are reared to supersede an old queen, if reared while the old queen is still in the hive. In both of these cases the bees are not *compelled* to rear a queen in haste for fear that they will not have brood of the right age to rear another for any length of time, as is the case when the queen is taken away, but, on the contrary, they take all the time needed, knowing that they still have a queen to fall back on should they fail from any cause in their first attempt. Now, when a colony swarms, as the Italians frequently do before queen-cells are started, I do not like queens reared in such a case any better than I do when the apiarist takes the queen away. It is the presence of the queen in the hive at the time the young queens are being reared that causes the bees to give the best of a cradle, care, and food, to the royal occupant. This cradle, care, and food, make all the difference in the world in the future usefulness of a queen, the same as does a mother's nursing, teaching, and love, to the child over that of a stranger who cares naught for it except that, in some way, it lives till it can help itself.

I could go on at length and tell of the food left in the cell after the queen hatched; of how all the requisites are present to rear good queens, etc.; but that would not help any. It is sufficient for me to know that, on an average, queens reared while the old queen is in the hive prove to live one-third longer and do one-third more work than do those not so reared. G. M. DOOLITTLE.

Borodino, N. Y., Aug. 31, 1886.

Friend D., I do not know whether it makes any difference whether we call our Italians hybrids or something else, so long as we all agree that they are, all things considered, the best bees to be found; but I do not quite see the force of your reasoning, that they can not be a pure race because the queens vary so greatly in color. We have plants and animals of all colors, unless we take pains by careful selection to *fix* the colors.—Now, in regard to cells made under the impulse of natural swarming, do not Italians, as a rule, or, at least, a greater part of the time, send out a swarm before they start queen-cells? I have, a good many times, tried to prove by experiment, that queens reared while the old queen was in the hive, were superior; but so far it has not seemed to turn out that way. My experiments, however, in that direction, have been somewhat limited.

HONEY NOT SUITABLE FOR COOKERY.

MRS. CHADDOCK'S IDEAS IN REGARD TO IT.

WE were not to thrash till next Saturday; but yesterday Mr. Chaddock came in and asked me if I could get ready for them to thrash to-day. I said, "No."

"Well," said he, "Mr. Ellison is here, and they have no other job; and if you *can* get ready I guess I will try to thrash to-morrow."

"But we have not a spoonful of sugar in the house," I demurred, "and thrashers always expect good things—cakes and puddings and pies."

But Mr. Chaddock kept on.

"Couldn't you start a new fashion," said he—"get up all the other good things that you can think of and leave out the sweet things—you have plenty of honey, you know?"

Then a thought flashed all over me, "I'll do it! Bring on your thrashers, and I'll sweeten every thing with honey."

We live four miles from town; and in this jam-up hurrying, no man, woman, nor child could be spared to go after sugar; and if we had them at all for weeks, we must have them now. I had several Mason jars full of honey that was left on the plates after we had eaten the comb honey off; and with this honey I made grape pies—green-grape pies; put in a layer of grapes, and half a layer more; sprinkle in a small handful of flour, then four table-spoonfuls of strained honey; put on top crust, and bake; also Dutch pies. Put a handful of flour in the bottom crust, and even it around; lay thin slices of good ripe apple closely over the bottom; put in a lump of butter as large as a hickory-nut; three table-spoonfuls of honey; grate a little nutmeg on top, and fill up with *boiling* water; it has no top crust. This is the famous Dutch pie that the belles of Illinois bake to hand out to their beaux on Sunday night when they come home from buggy-riding, only they make it with sugar instead of honey. I made some blackberry pies too, and sweetened them with honey; and we made cakes, and cooked apple sauce. As Josiah Allen's wife says, "Every thing went off well"—victuals all eaten up slick and clean, a compliment to the cook. But I don't like to use honey for cooking-purposes. In the first place, it is *not* cheaper than sugar; and in the second place, it doesn't make things taste quite right; and in the third place it is smeary.

THRASHING-MACHINES AND THEIR IMPROVEMENT.

Thirty years ago or so I used to help my father thrash. He used a flail, and we children gathered up and carried out the straw after the grain was beaten out. We had a smooth mud-floored thrashing-floor between the hay end and the horse end of our barn, and there we toiled day after day. As I sit here writing I see the steam-thrasher at work. They began at eleven o'clock, and in one half-hour more they will have thrashed twenty acres of heavy oats. They can thrash 2000 bushels in a day as easily as any thing. The little black engine, puffing its black smoke all day long, does the work of twelve horses, and it eats only coal and water. I like to see a steam-thrasher at work. It just about comes up to my idea of business. I like to see four men on the rick when one used to be enough, and a whole string of men on the strawstack handing the straw to each other. I like to see three teams hurrying away with side-boards on, level full; I like to see the sooty engineer raking the fire and throwing in coal; I like to see the boys hurrying with the water for the thirsty men, and all the rush and roar of it. I think if I lived in Paris I should be a Communist; if in Chicago or St. Louis, I'd be an Anarchist and shoot policemen. As it is, I take a wild delight in having thrashers, harvesters, or any thing to break this everlasting monotony. They have finished thrashing now. It is seven o'clock; and since eleven this morning they have thrashed 1027 bushels of oats, machine measure. It will weigh out eleven or twelve hundred. They could have thrashed more, but they broke a rod or spring or something, and had to send a man four miles to a blacksmith to get it mended. That took about an hour and a half.

MAHALA B. CHADDOCK.

Vermont, Illinois.

My good friend Mrs. C., the reason why honey will not answer as well for sweetening pies, and other things of a like nature, is because there is too much fruit-juice already; and while sugar would take up this fruit-juice, honey simply becomes diluted by being added to it. Honey is not good to put on apple-pudding, for the same reason. It tastes watery, and somewhat insipid, while even *brown* sugar, with a little butter, is delicious. You can remedy the matter somewhat, by using candied honey from which the liquid portion has been thoroughly drained. If honey is not cheaper than sugar now, it bids fair to be very soon.—I agree with you in liking to see business going on; but I do not believe I should ever want to see the monotony of life broken by becoming an *Anarchist.* — At our recent State Fair I saw arrangements that do away with the hard labor of the *stackers*, to a great extent, and I presume that a few years more will show far *greater* improvements in this branch of farm industry.

AN A B C'S OBSERVATIONS.

WHAT KIND OF A BRUSH SHALL WE USE IN GETTING BEES OF THE COMBS?

NOTICING in a late GLEANINGS an article from "Josepho," something about brushing vs. shaking bees from the comb, I feel like adding my experience, which may be useful to some. I think "Josepho" must work with black bees only; for while I have found them easily shaken off, I find it very difficult to shake Italians from the combs; besides, sometimes I wish to get bees from combs containing more or less unsealed honey, and the honey shakes out. I have used the Davis and other similar brushes, and been provoked by the bees attacking the brush, struggling frantically into the bristles, and calling for help until the thing was full of angry bees, and the air too, for that matter, for anger is contagious, especially in a bee-hive. I felt like throwing the thing away, and did sometimes, when the bees mistook my hand for the brush.

One day, after I got a comb in hand I found I had left the brush at the house; so I pulled some green timothy straws and used them. I noticed at once that the bees did not return to fight. Afterward I made brushes by cutting the straw about 14 in. long, about 20 of them, binding about 4 inches from one end for a hand-hold. I laid them lengthwise on the comb, brushing the bees quite as readily as with any brush; and after a month's use in the apiary I did not notice a single instance where the bees seemed angered at the brush. I suppose, having been accustomed to being brushed from flowers by the waving blades of grass, they took it as a matter of course. Now, I suggest that brushes be made with long splints of buckeye or rattan, stained green, to resemble grass-blades, and see how the bees seem disposed toward them. The grass itself is not durable enough to be satisfactory. Now, Mr. Editor, I think I see you scratching down at the end of this, that old bee-keepers knew all about this long ago, and had discarded it, or that you had decided that bees were color-blind, and that color could make no difference.

DO BEES DISTINGUISH COLORS?

Speaking of color, bees, as well as every thing else, seem to accept red as the gage of battle. One day, having torn the wristband of my under-shirt (red flannel) so that a small portion was exposed to view, the bees attacked it vigorously, and to the exclusion of every place else where they might have stung.

COMB-BUCKET, HOW TO IMPROVE.

I want you, friend Root, to improve your comb-bucket in two respects. I want you to put legs to it, to extend down and out two or three inches, so that it may be set down on the grass without tipping over of its own weight; and instead of two wooden handles, make one a kind of sheet hook, to hook over the other, making only one in the hand. It is very difficult to hold the two when carrying the bucket full of combs. BEE-KEEPER.

Charleston, Ill.

No, friend Bee-Keeper, I am not going to say that grass was discarded long ago, and I very much doubt if a brush can be invented that will work as well as a fresh bunch of grass, or a bunch of clover.—Legs on a comb-bucket would cost money, and would also be unwieldy to ship. Have a lawn-mower, and keep the grass shaved off close.

FUN WITH THE BEES.

HOW MY BEES HAVE GONE WILD—THE OTHER SIDE OF BEE-KEEPING.

I TELL you, I have had fun with the bees this year, or else the bees have had fun with me. The "fun" may be said to have commenced May 18th, when a swarm issued about three weeks earlier than ever before. At that time the meads were growing white with clover, and I went to clapping on surplus arrangements, and dividing. But owing to an accident which had crippled me for several weeks in the spring, and the fact that the season had set in so much earlier than usual, I was not prepared for it. I had a plan I had resolved to try. I wanted, and still want, as it happens, to control the wild, everlasting swarming instincts of my bees. I did with a dozen or fifteen according to my notion, but I could not get around fast enough. I had to quit dividing, prepare the section cases, and put them on. I could not do that in a day. In the mean time the bees were sending off their skirmishing parties, and ere long the great swarming armies were upon me. Among them were some from those I had swarmed myself. I grinned a "just as I expected," and let them swarm. It was fun to see the bees go to work so heavily in the boxes, and how I laughed to take off some fine white sections about the day in the year that I had formerly seen bees first go lightly to work in them! About the same time I laughingly shouted, "Well, they are enterprising," when I beheld my 18th-of-May queen lead off a second swarm, one day earlier than I had ever had a swarm before. The season was now upon me. You all know what that means. I had little time to swarm artificially. I could only put together frames and sections, take off honey, hive swarms, and do the making and mending I found necessary. Soon one after another of those that had swarmed and been hived on the old stand followed the example of the first, and swarmed again; also several of those I had divided. Thus far all these unwelcome swarms, I found had been hived partly on frames wholly or partly filled with old comb. I smilingly decided that I would know how to fix them next year!

"Bees," said I, "when they swarm, want to set up housekeeping anew." I had long thought it, and now I was sure of it. Yes, I laughed in joy at the discovery. But the laugh turned against me, as you will soon find. Just about now so many things happened that I can not keep up in the telling. I had started into the season with 57 stands of bees and a queenless one, and about 35 empty hives available. I was going to keep down swarming, and bend all our resources and powers to the production of honey, that I was as sure of as the world, etc. Thus far I had controlled it in such a manner that, at the rate they were going, three days bade fair to utterly exhaust my stock of hives. No frame hives to be obtained, except two L. hives, about as much like mine as black is like green; no lumber to make any box hives, which I did not want any way; no time to make them or get anybody else to make them; no time, in fact, to do any thing but what was before me. Every one else was as busy as the bees were, and, as crowded as I was, what should I do? Well, it was part of my plan to set two old colonies side by side after swarming, and, after the queens had hatched, to unite them. I put the extra frames in the upper story, and ran for extracted honey. The frames of some colony that recently swarmed I would distribute among the colonies thus formed. These young queens, contrary to all precedent and all reason, went to swarming pretty soon after they got to laying. Also some weak colonies that I had utilized some of these old colonies to strengthen, swarmed as soon as they felt big enough. Also, if I chanced to put a frame containing unsealed larvæ into a hive with a cell nearly ready to hatch, they would start a new set of cells, and swarm; then again two or three weeks after I thought it was all over, here would come another puny swarm. All these things happened a number of times. Of course, these proceedings filled up my hives all the faster.

Every day for nearly two weeks, except a couple of very rainy ones (and I tell you I smiled broadly at the chance they gave me to get a little ahead), I would run down to about two hives to none available. So about six o'clock P. M. I would start to empty some hives for—to-morrow. I usually hived my swarms on six frames. Now I would take off supers, remove dummies, and poke a frame any where I could find to poke it. Colonies of to-day's swarming that I had set off from the old stand I would tear to pieces, or perhaps carry them mostly to the upper story of some hive that ought not to swarm. Several hives now held 12 to 20 frames. I had to put my swarms on empty frames. Accordingly I had to nail a lot of new ones that I had not expected to want, and fix fdn. in them. No time for *ennui*. I was kept on a hop, skip, and jump all the time. But, not content with contrariness, those crazy bugs must add to it capriciousness. I hived a big swarm one Sunday. The next day it arose and left. The new disease caught and ran like wild-fire. I would hive swarm number 40 as near as they would hive. Perhaps they would nearly all go in. If they did they would crawl out and cluster in front, on top and all around, more or less. All the way from half an hour to 24 hours they would swarm out and settle, to be hived again or go off, or simply adjourn to the front part of another hive—sometimes all three or less. It did beat all how they would cluster in front of another hive, and then, like the dog in the manger, neither do any thing themselves nor let anybody else do. "Well, that is funny," was my exasperated exclamation, a dozen or so times during the progress of these proceedings. Now I found out that many of my absconders were hived on empty frames. Indeed, I had ceased to put any old comb into the hives, before the swarming and absconding fever had reached its height. My bubble theory had burst. Several of my baby-swarms I put back, and half of them stayed. Of course, two or more swarms often went together. I would hive them together—it was the best I could do. Several times such a colony became queenless. I think this was because one queen was a layer and the other a virgin, and the bees of each swarm balled the queen of the other.

One of the hottest days—hot in more ways than one—a swarm settled high up and far out on a hickory limb out in the pasture. Soon another clustered on a young apple-tree. I was preparing to hive the one I could get at easiest, when another started to settle with it. I wrapped my sheet around it and held it there awhile, sweating at the same time. But I suppose the queen got ahead of me, for those bees would not stop any where else. I had no time to waste, so I gave it up. After they had settled, I shook them down on to the sheet. In the meantime my high-minded swarm had adjourned to the end of a lofty limb of another hickory in the other pasture on the opposite side of the apiary (some time afterward I saw another swarm make a similar change of lodgings). I was lugging my step-ladder, hive, sheet, and long-handled pruning-knife to their settlement, when I beheld them all at once move down to the front of another hive, the occupants of which did not know what to do with themselves. I thought that was as funny doings as bees could do. But the two swarms down by the apple-sprout did funnier still. When I came back to them they had blackened that big ten-frame two story hive. I did not move them—it was not worth while, even if I could.

The next morning I walked down the path just in time to see a swarm rise and start off. But in a minute another swarm issued from the hive, and another swarm sailed off about twenty paces behind the first, and the two moved like a funeral procession down the fence-row. As I stood and watched this proceeding I thought, "Surely not many an old apiarist has seen such a show as that." It was the funniest caper I had beheld them cut. I had to run in and tell mother.

Do folks ask, "Why did you not hunt out the queen, divide the swarm, clip her wings, cut out cells? or do this or that or the other, or something else?" Now, I do not want to take six sheets, in addition to what I have written, to tell why. But imagine, if you will, a little, nervous, dyspeptic fellow, with back and limbs perpetually getting the aches, muscles as soft as those of a sweet-sixteen society girl, joints so stiff and sore that, after sitting at the dinner-table twenty minutes when he meant to take only ten, he would get up and start off like a buck-kneed string-halt colt; supers getting full, weeds and sour docks growing that he did want so much to get shut off; letters lying unanswered, etc., and it may be not as much *sense* as Heddon or Root. I tell you, it was easier to *say* than do. You see, a weakling can not do as well, even at bee-keeping, as a stout healthy man. GEO. F. ROBBINS, 57—93.

Mechanicsburg, Ill., Aug. 20, 1886.

Why, friend R., you did have "business" in real earnest, did you not? What queer opinions we often get from reading the letters of our correspondents! Somehow I had got the idea that you were a great big man, like Doolittle and some of the others. One of *my* besetting sins is to make great preparations, in the way of business, for booms that never come to pass; but once in a while I happen to hit it, and then you do not know how I enjoy having plenty of every thing ready to take care of the business when it does come. I, too, am small, and not very strong, and quite often nervous and dyspeptic; but the stout, healthy men do not always move things very much further or very much faster than I do; so take heart, friend R.; the victory is not always to the strong.—By the way, you did not tell us how much money you made, after all your trials and tribulations had been passed through. I think you have learned something by experience, and next time you will probably find yourself a little cooler, and a little more master of the situation.

FOUL BROOD.

DOES IT EVER ORIGINATE FROM OVERHEATING THE BROOD?

WHEN a bee-keeper finds foul brood among his bees, about the first thing he thinks of is, How did it come there? About the first of June, 1874, I bought of N. N. Betsinger, then at Marcellus Falls, four swarms of bees. The frames of brood and bees were put into boxes, which were prepared for that purpose by making a small hole in each end, with wire screen over them. The day we went after them we had to wear our overcoats, it was so cold riding. We stayed over night. Next morning we put the bees in the boxes early in the morning, and started for home, about 30 miles. The sun came up bright and clear, and proved as much too warm for comfort as the day before had been too cool. With our calls and journey, the bees were shut in the boxes all day, and let out after sun down; with the warm weather outside, and the closeness of the boxes, a few of the combs (which were *old* ones, with very little honey in them) broke from the frames. In about 30 days I found foul brood in all of the four swarms. Later on I saw Mr. Betsinger. He said the bees were all right when we left his place; I also saw the bees and brood when Mr. Betsinger put them in the boxes, and saw nothing wrong about them then. Evidently the foul brood was caused by the great heat in the boxes, together with the neglect of the bees, through the day, to care for the unsealed brood.

Two of the young queens that were in other swarms, and mated that summer in my apiary, had this peculiarity about them. Some of the larvæ, when about ready for the bees to seal over, died in the cells: also some that *were* sealed over, and were formed bees with legs on them, died; but, unlike foul brood, this dead brood was only where the two queens were, and was not contagious.

I removed those two queens, and put others in their places, and the whole cause was removed.

As a proof that it was the heat in the boxes that caused the foul brood in the first instance, I will give my experience again, as late as 1885.

A very warm day, my bees were swarming at a tremendous rate. I had three swarms then in the air, when another swarm started to come out. I wished them to wait a few minutes, that I might care for the first three, and I put a board partly covered with wire screen over a hole as large as a man's hand with fingers and thumb straightened out, over the portico, fastening the bees in. While caring for the swarms that were out, I was detained longer than I expected; and when I returned to the hive where I had shut the bees in, I found the honey running out at the bottom on to the ground. I removed the screen-board, took the hive into the shade, opened the whole hive to the air, but it was too late; part of the bees were then dead; the others, though they could move a little, died very soon.

Within the hour I put bees (no queen) on to these frames of brood, as a test whether this state of things would produce foul brood or not, within five days *all the unsealed* and part of the sealed brood was a putrid mass, which the bees could never remove.

Now, from my past experience I think it safe to say that foul brood often originates in the apiary where it is discovered, by the careless operator, who leaves the brood from hives exposed to the scorching rays of the sun, thereby scalding the larvæ in such numbers that the bees can not remove them in time to escape the dreaded disease, foul brood, by the brood becoming a putrid mass. After a time the dead larvæ dry down, and the bees remove a part of it, then the queen lays in the same cells, and surely the larvæ will die and become a putrid mass, the same as the first. Usually, before the operator discovers that he has foul brood, he has changed combs, or in some other way has got into other hives; then the *question*, How *did* I get foul brood? H. D. MASON.

Fabius, N. Y., Aug. 20, 1886.

Friend M., your suggestions would be good had it not been well proven that foul brood is a plant, and can no more start spontaneously—*i. e.*, without seed—than can a hill of corn. Dead brood may start putrefaction, and this may present much the appearance of foul brood, but the seeds of foul brood must be present or it will never be foul brood at all. I scanned your communication with much interest to see if you did not, somewhere, mention whether or not friend Betsinger has recently had foul brood in his apiary.

CELLAR WINTERING AND SUB-EARTH VENTILATOR-PIPES.

DISCUSSED BY MR. HUTCHINSON AND DR. MILLER.

FRIEND MILLER:—I was very much interested in your articles on cellar wintering.

1. Let me ask you if *two* or more small sizes of tile laid in the same trench would not be better than one large tile, simply for this reason: There would be greater opportunity for the influence of the earth's warmth upon the air. The distance around a four-inch tile, where it comes in contact with the earth, is about one foot, while its carrying capacity is represented by 163 gallons per minute. An eight-inch tile has a surface of about twenty-four inches, only twice that of a four-inch; yet its carrying capacity is represented by 923 gallons per minute, or nearly six times as great. Do you see? Of course, the expense would be greater in using several small tile.

2. In your experiment in stopping up your four-inch tile, how far in from the inner mouth of the tile did you put your thermometer, far enough so that the warmth from the cellar would not affect it?

3. Have you ever noticed how many degrees the air is warmed in passing through your tile, or does it differ?

4. How did you learn that 100 ft. was long enough for your four-inch tile?

5. Your stoves are not in the same apartments as are the bees, are they?

6. Do you use them to cause ventilation or to warm the cellar, or both?

7. Why isn't your cellar warm enough without them?

8. At what temperature do you keep it?

I presume I have asked enough for one time.

Fraternally yours, W. Z. HUTCHINSON.

Rogersville, Mich.

Dr. Miller replies to the above:

1. Two or more tile of a given capacity will warm the air more than a single tile of the same capacity, as explained in the question, provided that length of pipe has not been reached where the temperature of the air in each case has become that of the surrounding earth. In this case, of course, the smaller tile would have no advantage.

I had at one time decided to lay two tiles in the same trench, to have the advantage of raising the air to a higher temperature; but upon further thought and experiment I concluded I could more satisfactorily and cheaply accomplish the same thing another way. An eight-inch tile will cost less than two four-inch tiles; and to make it bring the air to the same temperature, all that is necessary is to partly close the aperture where it enters the cellar, so as to make the air flow in at the same rate of speed at which it flows in the smaller tiles. In this case you would have the advantage of being able at any time, if you so desired, to open up the pipe to its full capacity and flush out all the air of the cellar. I think now of putting a ten-inch tile in the drain for my shop cellar; for, no matter how large, it can at any time be closed down to the capacity of a small tile; but if a smaller tile is laid it can not be enlarged.

2. The thermometer was thrust into the pipe as far as possible without putting it beyond reach to draw it out again. I hardly think the warmth of the cellar would have much effect upon it, as the contents of the whole tube would freely mix.

3. The number of degrees the air is warmed in passing through the tile depends mainly on the outside temperature. One day the air may be warmed five degrees in passing through, and the next day twenty degrees. The air enters the cellar, say at 38°; if the outer air is 33°, the air is warmed 5°. If the outer air the next day is 18° it must, of course, be warmed 20° to enter at 38°. In other words, the air enters the cellar at about the same temperature from day to day, no matter what the weather, and there is no perceptible change with

the change of weather, only as it changes very slowly in the course of the winter, and that through but a small number of degrees, growing a little colder as the winter advances.

4. I put the thermometer in the tube and then closed the tube. After remaining closed several hours, the thermometer showed the same temperature, substantially, as when entirely open. Of course, a longer tube could raise the air no higher than it would be when standing still in the pipe; and as 100 ft. raised it to that temperature, a longer tube could raise it no higher.

5. My stoves are in the same apartment as the bees, the nearest hives being about four feet from the stoves. When I used wood-stoves I put a board covered with zinc between the stove and the hives. Since using coal-stoves I use no such precaution, and I think the colonies nearest the stoves winter as well as others.

6. I just used fires occasionally to warm the cellar when the bees began to be uneasy in a cold spell, but concluded afterward that they did more good by increasing ventilation. I am now uncertain whether the heating or ventilating is more important, but believe both essential to best results.

7. Because, without stoves, the best cellars in this locality hardly keep above the freezing-point in the coldest spells. Possibly, some time I may succeed in warming by a sub-earth tube.

8. I try to keep it from 43° to 45°.

I shall be thankful for the severest criticism from friend Hutchinson, or some of our sharp-eyed Canadian friends; in fact, from any one; for in the matter of warming and ventilating I am as yet a novice. C. C. MILLER.

Marengo, Ill., Sept., 1886.

NOTES FROM THE BANNER APIARY.

NO. 82.

THE LAST NUMBER OF GLEANINGS.

IT seems to me that it was an especially *good* number. I should like to notice a few points.

THE WAX QUESTION, AGAIN.

Is not the only way in which this question *can* be settled—i. e., so as to be of any *practical* benefit to bee-keepers—to do as I have been doing the past four years; viz., hive part of the swarms on fdn., and part on empty frames? What do we care how many *pounds* of honey are consumed in the production of a pound of wax, if we *do* know that it is profitable to allow the bees to build their combs at certain times and in certain places, and at others it is better to furnish them fdn.? I feel that we have been using fdn. too indiscriminately; that to know *exactly* when and where, to me is a great question. I *know* that for *me* to use it in the brood-chamber when hiving swarms, is to lose money, and I see by this last issue of GLEANINGS that others are arriving at the same conclusion.

IMPLEMENTS AND LABOR.

It is a pleasure to see an article once more in GLEANINGS, signed "J. M. Shuck." His articles are always timely, valuable, and well written. When he says, "The time required to manipulate the invertible hive for the production of honey is not one-fourth the time required for a non-invertible hive. *There is the gage*, come who may," he very tersely covers *nearly* the whole question. This question of implements and labor is an important one, and I feel that Bro. Doolittle does not take the correct view of it. The quotation that he gives from somebody's letter; viz., "The use of my hives and surplus-cases will give you more honey than you now produce, with one-half the labor," ought not to be construed to mean that the use of certain hives would enable the bees to gather any more honey, any more than the use of the mowing-machine, horse rake and fork, would enable us to secure more *hay* per acre; but the use of these improved implements enables us to secure the same results with *less labor*.

BLACK BEES; ARE THEY EQUAL TO OR BETTER THAN ITALIANS FOR COMB HONEY?

The point that you make, Mr. Editor, in your foot-note to Mr. Coleman's article, in regard to his having *all* black bees, hence could not make a just comparison, is a reasonable one. I think, too, that the majority of bee-keepers favor the Italians; but for the production of *comb honey* I doubt if there is a better bee than the black bee; *possibly* a cross between them and the Italian is better; but were I to choose a pure variety I would unhesitatingly choose the blacks. When handling combs, looking for queens, and the like, Italians are more pleasant to handle; but in raising comb honey this is something we seldom have to do. Ever since I began the production of comb honey I have had from five to twenty colonies of blacks (controlling, of course, the production of drones), and these black colonies have *stored as much honey upon an average as have the Italians*, while the honey is of finer appearance. This very propensity of the blacks, to run off the combs when being handled, is really valuable when we manage bees by handling *hives* instead of combs, as the hive is more easily cleared of bees, just the same as I can clear a case of sections from black bees twice as quickly as I can when the bees are Italians. I *do* think the blacks are more inclined to rob and to suffer from the attacks of the moth; but as I have yet to lose my first dollar from *either* source, I consider these minor points.

W. Z. HUTCHINSON.

Rogersville, Genesee Co., Mich., Sept., 1886.

FOUL BROOD.

"ALMOST SCARED."

FRIEND ROOT:—I can not but feel sorry for you when I think of "the dire calamity" which has befallen you; but, are you *sure* you *have foul brood?* I consider myself an old veteran in the foul-brood business, and you just look on page 388 of the *Canadian Bee Journal*, and see how near I came to being "almost scared" about foul brood here in our apiary, where every thing is nice and new, and every precaution had been taken to not have the disease in our new apiary. If you have the "real stuff," then you are doing right to burn up the combs. But, be it whatever it may, turn on the steam and give it a warming-up, anyhow. A. W. OSBURN.

Havana, Cuba, W. I., Aug. 25, 1886.

Yes, friend O., we feel sure we have the "real stuff." In spite of all we can do, it continues to exist in our apiary. See Our Own Apiary, this issue.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from Aug. 15.

CHAPTER XXIII.

We remember . . . the cucumbers, and the melons, and the leeks, and the onions, and the garlic, which we did eat in Egypt freely.—NUM. 11:5.

Continuing the conversation which was interrupted by our last chapter, I remarked:

"Then, my friend, this wonderful corn has been brought up to its present perfection by your own efforts, has it?"

"Well, somewhat; but it was a very good corn when I first began growing it."

"What do you call it?"

"It is the Crosby Early sugar corn."

We talked about a good many other things; and as I bade him good-day I thanked him for the important facts he had furnished me. He in turn thanked me for the pleasant chat I had given him. I started off at a rapid rate, for my time in Arlington was worth to me—how much? Well, something like five or ten dollars an hour; that is, I had paid out an amount of cash to come so far that would make every hour of my stay cost me something like five or ten dollars, and therefore even the minutes were precious. I had not gone far, however, before I thought I heard somebody behind me. It was our old friend. As he came up he remarked, "If you will write your name and address on a paper I will send you some of the seed of that corn by mail when it gets ripe."

"Why, my good friend, I am much obliged to *you;* and if you will give me your name also, I will with pleasure send you our bee-journal for a year, that I was talking to you about."

He said he was getting to be so old he could not read very much; but he said he would be very glad to look at it, especially since I told him it contained more or less pictures every month. When I came to write his name in my memorandum-book, what do you think it was? Why, this: *Josiah Crosby.* I looked up in astonishment as I put out my hand again to him.

"Why, my friend, is it true that I have been talking this morning with the originator of the Crosby Early sugar corn?" He bowed and smiled.

Now, dear friends, I warn you, before you send to friend Crosby for some of his sweet corn to plant, that unless you have the Arlington soil, or soil as they manure it, your corn will turn out like that which we have already, pretty much.

I noticed on friend Crosby's place they were pulling up cabbage-stumps, and drawing them off in carts to a compost heap. I noticed afterward, also, that, when composted with manure, they gave a decidedly rich smell. I asked Mr. Crosby if they never fed them to stock; but he said there was not stock enough to consume the hundredth part of them. They are composted, and worked back into the ground again. I asked him if he had ever been able to make any estimate of their probable value for compost. He said he thought a ton of cabbage-stumps was worth pretty nearly if not quite as much as a ton of night-soil, which is largely used in the gardens of Arlington. Their plan of using night-soil is to make heaps of stable manure in the fields, and then hollow out the center so as to make a cavity. The night-soil is now drawn in carts and dumped into this cavity. The manure is now thrown over it, and the whole heap is forked over from time to time until it becomes a dark homogeneous mass, ready to be spread and plowed under.

Dandelions are a favorite crop in Arlington. Sometimes we found half an acre of them, and they told me that they found them to be a very profitable crop. In early spring the dandelions bring $6.00 a barrel, for early greens. It takes two years to get a crop; that is, the seed is sown in the spring, and the plants are cut for market the next spring. These cultivated dandelions are very much larger than our wild ones growing in the fields. The plant is cut for market just before it begins to blossom.

RAISING CUCUMBERS IN GREENHOUSES, FOR THE BOSTON MARKET.

Mr. W. W. Rawson is the great cucumber-man of Arlington. He has seven greenhouses devoted exclusively to raising cucumbers. These seven greenhouses contain over 1000 hills. The vines are trained on a trellis running about a foot below the sashes. My attendant told me they picked one day 2000 cucumbers which were sold in the winter at 30 cts. each, or $600 for one day's picking. They warm the houses by steam. It has generally been thought a difficult matter to raise cucumbers under glass; but my attendant said there was not any trouble at all. I suppose there is no trouble, because he has learned just how to do it, and so it becomes as simple as many other things which we do daily, and think nothing about it whatever.

"My friend, how about fertilizing the blossoms? Where you raise cucumbers or melons under glass, you are obliged to carry the pollen from one flower to another, are you not?"

"Why, bless your heart, Mr. Root, *we* don't carry the pollen — the *bees* do that."

I was all attention all at once, you may be sure; but he seemed to take it so much as a matter of course that I began wondering whether he really knew what he was saying, so I ventured — but while I spoke, my mind ran vividly over my experiments with bees in a greenhouse years ago, and this is what I said:

"But do you keep *bees* all winter long in these greenhouses?"

"Why, yes; to be sure, we do."

"But where are they now? I don't see any."

"Oh! we take them outdoors as soon as it is safe to have all the doors and windows open."

Perhaps he thought it took a good deal to satisfy my curiosity, so I ventured to ask if I might see the bees where they were now. Sure enough, there were seven hives of bees. They were in old-fashioned tall box hives, and set on a bench side by side. They did not get any honey from them; in fact, he said they did not pay any attention to that part. All *they* keep them for is to make the *cucumbers* bear, and I tell you they *do* bear, judging from the specimens I saw hanging on the trellis, even as late as the 28th of July. I walked up to the extrance, scanned the bees closely to see if there was any Italian blood; but they were just common black bees — nothing more. He said they bought them for Italians, and I promised to send him our bee-journal, to post him on bees in return for the way he had posted me on cucumbers.

"But, my friend, do the bees not die sometimes? Don't they fly up against the glass, and worry themselves to death, and then fall on the ground?"

"Oh! they do to some extent when we first bring them into the house; and sometimes a colony does not seem to work well on the cucumber-blossoms. In that case we try another. The price of a colony of bees is not much compared with the product of our greenhouses. As a general thing, after the little fellows get to work on the blossoms they find their way back to the hive as well as if they were out of doors. And what a humming they do make, some of the coldest winter days, when the sun comes down so as to brighten up every thing!"

I asked him if the cucumbers did not require a very high temperature. He said they did better with a temperature between 70 and 80 degrees; but he did not think it was a matter of so very much importance after all. Of course, they grew faster when the temperature was just right.

While my friend was talking I could not help smiling at the recollection of an incident related by Mr. L. C. Root at our little bee-convention at Versailles, N. Y. He said, during his speech, that a lady living near him complained about his keeping so many bees; but when asked to tell just where they inconvenienced her, her principal grievance was that she was unable to raise a single *cucumber* in her garden since he had been keeping so many bees in the neighborhood. Just think of it, friends! I do not mean to be hard on the poor lady; but it is well worth our while to stop a minute and consider how much foolish superstition is passing current among people, in place of real science. As I stood in front of that row of seven box hives of black bees, I stood for a moment in silent wonder, to think how two such great industries were moving along in our nation, and yet the busy brains of the one industry knew hardly any thing about the busy brains of the other. My friend by my side knew all about cucumbers, but he did not know a thing about bees. I am not sure he knew there was such a thing as a movable-comb hive in existence, and yet he was a bee-*keeper*. He could not raise cucumbers without being a bee-keeper. I knew all about bees, and could have pulled all his old box hives to pieces—could have shown him the queen, and talked for *days* to him without having exhausted the subject of bee culture, and yet I knew comparatively nothing in regard to *his* industry.

Now, another point comes in right here: On one of the benches I saw about a dozen of the most beautiful cucumbers, it seems to me, that were ever produced since the world began. May be the ancient Egyptians used to have some that would compare with this lot, but I hardly think they did. They were not only larger than any thing I ever saw before, but they were beautifully symmetrical in shape, and of a pearly whiteness that made them wonderfully attractive to the eye.

My guide seemed inclined to pass along; but I called to him to hold on a bit.

"My friend, what kind of cucumbers are those? and how in the world does it come that such a beautiful lot of them should be left here in this out-of-the-way place?"

"Why, Mr. Root, those extra-fine cucumbers are saved for the seeds, and these seeds are to be planted in the greenhouses next year. They are the most perfect and finest specimens we can select from our whole crop."

"But will you sell me some seed from these? I would give their weight in gold, almost, for a few of them to get a start of that variety."

"Why, the variety is the 'White Spine' which we advertise; but I don't know whether the boss would let you have any seeds from *those* specimens or not. You will have to write to him about it."

I did write to him, you may be sure, just as soon as I got home, and here is his reply:

> *Mr. A. I. Root:*—Your esteemed favor is at hand. Your order will be mailed to-day, except the Rawson's White Spine cucumber. This stock we at present have not got, but later on will send you some seed taken from Mr. Rawson's own stock, the same stock as "those cucumbers" were from. Mr. R. regrets that he was out West when you were at his place, as he might have helped to show you round. W. W. RAWSON & CO.
>
> Boston, Mass., Aug. 5, 1886.

Now, then, no doubt all of our readers are just like myself, and want a few of those choice seeds. I suppose they are really stock seeds, such as friend Green alluded to on page 607 of GLEANINGS; and you know stock seed is not often for sale. I would gladly divide with you, but the few seeds I am to get would not begin to go around among so many friends. You can buy the seed of the Arlington "White Spine" cucumber by sending to Mr. W. W. Rawson, Arlington, Mass. But the great point for us is right here: Just think of the wonderful importance of having the very best seed that can be procured, when the crop of cucumbers is to amount to several thousand dollars! Those who have sold cucumbers in the market very well know how much more they can get for a nice, handsome-shaped cucumber, compared with a crooked, ungainly one; and, without question, choice seeds from the finest specimens will be more apt to give us a handsome crop of cucumbers than seed collected from refuse, crooked ones. And what is true of cucumbers is true of every thing else. It is of as much importance to please the eye of customers as to please the palate; and God has placed it within our reach to please both in a way we perhaps little know of now. Now, then, in saving your seeds for next year, or next summer's planting, remember, "Whatsoever a man soweth, that shall he also reap." I will try to save a lot of seed from the stock seed I am to have, and then I will gladly furnish you all, if you prefer to buy of me.

Some of the friends have written to me, making inquiries in regard to the culture of cucumbers under glass, but I suspect it will be almost impossible to lay down, in books, rules that will enable you to succeed without a good deal of "cutting and trying," as it were. Try one or two hills at first, in a small greenhouse; and when you succeed with a few, try it on a larger scale. But before you go into it very much, be sure you have a market for them, after you get them raised. We purchased some cucumbers early in April, and tried them on our wagon. But nobody had been used to seeing cucumbers at that season of the year, and they treated them about as they did our lettuce in January. We tried at first to get 10 cts. apiece for them; then we tried to close them out at 5 cts., and finally at 3 cts. But it was not the time of year for cucumbers in Medina, and folks would not pay as much for them then as they afterward paid in the latter part of June. In fact, just a little before the usual time for raising cucumbers in Medina, we got 5 cts. apiece for a dozen or more every day, and could not supply the demand. So you see you will have to work up a market at the same time you learn how to raise cucumbers. May be you will wonder why I chose this singular text. Well, it seemed to me a little funny that the ancient Egyptians used to relish garden vegetables just as we do—cucumbers, melons, leeks, onions, and garlic. Somehow my heart warms toward them in reading this little verse, for it brings me nearer to them. They were human, just as we are, with human wants and longings.

CHAPTER XXIV.

Seest thou a man diligent in his business? he shall stand before kings; he shall not stand before mean men.—Prov. 22:29.

On the opposite page you will find a sketch of friend Rawson's ten acres under glass. When I first came on the grounds I turned up by the building in the foreground which you see surmounted by a windmill. I passed along by the alley on the left-hand side of the picture until I found a boy hoeing lettuce. I inquired for Mr. Rawson, and the boy told me Mr. R. was absent on a vacation. But he further remarked, that the best man to show me around would be the foreman of the greenhouses, whom I would find at work in the building mentioned. I have forgotten the young man's name, but he was very obliging and communicative. He went all over the grounds with me you see in the picture. The four large greenhouses in the foreground are those used for raising cucumbers. The three long ones on the left-hand side of the picture have movable sash, and these sash are taken clear off in the summer time. This latter plan of greenhouses has some very great advantages, especially the one permitting the sash to be removed, so we can reap the benefit of summer showers. These greenhouses are all warmed by steam, as I have before remarked, and my attendant informed me they had no trouble whatever in using steam in place of hot water. You can run your pipes up and down anywhere you wish, providing you remember to put a drip-pipe wherever there is a low point or depression in the steam-pipes. This drip-pipe is to have a valve, which is kept open just enough to let the condensed water get out of the way. The back part of the grounds is covered with hot-beds and cold frames. During severe weather they use large mats made of very tall rye straw. In fact, they raise a patch of rye every year in this wonderfully rich ground, in order to get straws six or more feet in length for making mats. The mats are woven by the watchman in the night time. When these mats are removed from the glass, as they always are when the sun shines, they must be placed somewhere. Now, even a simple matter like this is sometimes quite a problem. If you lay them on the ground they will get wet, and rot; if you lean them against the fence the wind will blow them down, and the most convenient way Mr. Rawson finds to be a tight board fence set on a slant You will notice such fences at intervals among the hot-beds and cold frames. These fences also serve as windbreaks.

At the left of the picture you will notice a six-sided inclosure, with one side left open. This is for composting manure. It keeps the manure from getting scattered about in the dirt, and is easy of access from the open side. My attendant, though a young man, has entire charge of the heating arrangements, and he told me that, instead of employing expensive city plumbers, they cut their own pipes and put in their heating arrangements, according to their needs and requirements.

The building surmounted by the windmill contains the steam-engine used in pumping water when the wind does not blow. They always use wind in preference to steam when the wind blows. I believe that the boiler for heating the greenhouses is also in this building.

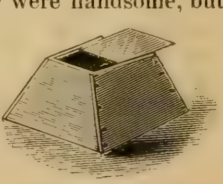
When I spoke of looking over the hundred-acre farm which also belongs to Mr. Rawson, my guide very obligingly asked me to take a seat in one of the market-wagons that was standing near the building, right where you see a wagon in the picture. The horse that drew the wagon was so well accustomed to his business that he took us wherever we wanted to go, almost without being told. I presume I asked more questions than some of the newly fledged scholars in A B C of bee culture.

I was particularly taken up with a field of Boston marrow squashes. The vines were so large for the time of year, and so exceedingly thrifty, I burst into exclamations of surprise.

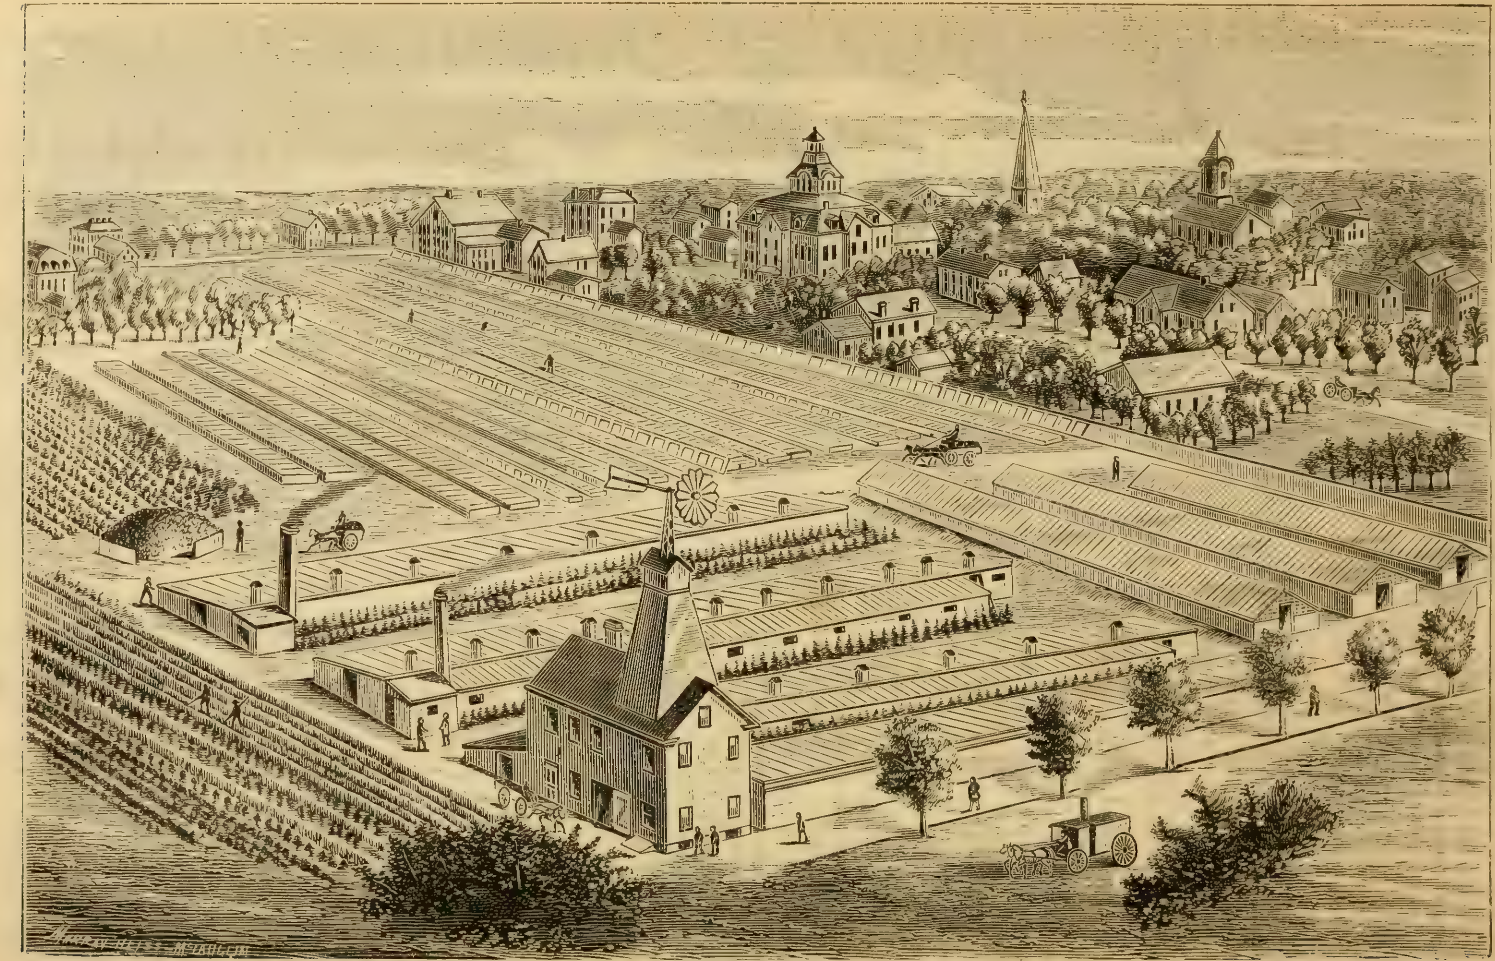
"Why, my friend, were these not raised in a greenhouse, and planted out here?"

"No, sir; the seeds were planted, and the vines grew right where you see them. Aren't they handsome?"

I admitted that they were handsome, but I didn't feel quite satisfied with his answer. Why, some of the squashes were almost ready to send to market, and it was not even the first of August yet. Before we got around, however, my greedy eyes caught



RAWSON'S BOX FOR STARTING SQUASHES, ETC.



W. W. RAWSON'S CUCUMBER GREENHOUSES AND HOT-BEDS, ARLINGTON, MASS.

sight of a heap of boxes like the one shown on the preceding page.

As he was driving past the heap of boxes, I asked him to hold on a bit.

"Will you please tell me what those boxes with sloping sides are for?"

"Why, that is a secret; but as you have got hold of it, I suppose I shall have to admit that they are what we use over those squashes you saw. You seemed surprised to see them so much in advance of the season. Well, those boxes are the things that did it."

These boxes are made of half-inch lumber, and of such size that a pane of glass 8x10 slides easily in grooves, as shown in the cut. The squash-ground is prepared in the best manner, the seeds planted, then these boxes are placed over the hills, banking the earth around to make it tight. The sun shines through the pane of glass, warms up the earth, and starts the seeds two or three weeks sooner than they would start without this protection. When the vines get large enough the lights of glass are slipped out, and the box serves as a protection from the bugs, as well as from the cold winds. Now, the great improvement in these boxes is, as you will notice, that they pack one within the other, so they can be nested and carried about, or stored away in a small compass. In fact, they are almost like solid lumber.

Of course, their use is not restricted to squashes alone. They can be used for cucumbers, melons, cauliflower, or any thing else that you discover by experience will bring a good price in your market a little in advance of the regular season. My opinion is, that they would pay well for forwarding early potatoes. Our town of Medina won't pay very much money for fancy vegetables at high prices; but they will pay from 40 to 50 cents a peck for early potatoes, and they will take a good many of them too. We are planning now to use 400 or 500 such boxes, to give our Early Ohio potatoes a big start next spring. I have ascertained by careful figuring, that these boxes can be furnished for 10 cents apiece, or 100 for about $8.50. Glass, 8 x 10, will cost you by the box not to exceed 3 cents per light. If you are careful not to break the glass, it is worth all it costs, almost any time. We have been using hand-glasses with a gable end of cloth; but they are unwieldy, and ricketty to handle. The boxes shown above can be moved about in a wagon, to put in place, and the lights of glass slipped in afterward, so as to avoid breakage; that is, the glass can be handled by itself, and the boxes by themselves.

Of course, the matter of finding a market for the stuff we raise is always before us, and is always one of the great important problems. While traveling, I took particular pains to see how largely vegetables and garden-produce entered into the bill of fare of our different places of refreshment. I was so absorbed with what I saw and learned at Arlington that I could hardly take time for my meals; but I knew that it was impossible for me to do good solid work during the few hours I was to stay, in hunting up valuable facts for you, my friends, without my regular meals; and when I waited in a restaurant for my dinner I began wondering whether the Arlington eating-houses would show on their tables the good things I saw abroad in the fields. Well, this first dinner consisted principally of rolls bought from the baker's wagon. The lady who kept the place went out to the wagon and purchased them while I was sitting at the table. Not a vegetable greeted me. For supper I stopped at the only hotel in Arlington. To get to the dining-room I was obliged to pass through a whisky-shop. The landlord explained that they had just finished supper, but he guessed the girl could find something for me. What she "found" was bread and butter—both bad; some greasy boiled ham—*very* bad; not a potato, not a vegetable of any kind. I concluded I should have to make up for the lack of other things by a piece of berry pie which she shoved at me toward the close of my meal. The berry pie was bad too, as well as the coffee. The girl acted as if she felt injured because I came in to supper after the rest had supped. There was one consolation, however: It did not take me long to finish my supper, and so I had the more time for the gardens. I thought that perhaps the landlord would name a moderate sum, in consideration that there was not much left after their regular meal: it was, however, "A half-dollar, sir." I presume likely his interest centered more on the contents of the bottles behind him than in giving a customer a "comfortable" meal. I wonder if the Arlington people have not got something like our Ohio Dow law by this time. If they have, mine host has probably gone out of the business, for he certainly could not make a living furnishing such suppers for half a dollar, for his patronage would soon be lost.

Now a word in regard to the girl who waited on me. Had this woman had the Savior's love in her heart, it would have been a pleasure for her to wait on a stranger, and hunt up the best that could be found for him under the circumstances. She knew, or might have known, that her employer received half a dollar for the supper she was to furnish, and it was her duty to reason something like this: "If we get half a dollar, we can well afford to give this stranger the best the house affords." One who is building up a business, or assisting to build up a business, feels thankful for patronage, and I do love to see people show their thanks in looks and actions, under such circumstances. A pleasant, cheerful willingness to wait on the great traveling public, is worth more than money in the bank to any man or woman who wants to succeed, whether such persons be gardeners or hotel-keepers.

Well, I did not succeed in finding any fine vegetables on the tables at Arlington, so I thought I would try the great city of Boston. I was told that the farming and gardening community generally stopped at the New-England Hotel, as it is quite near Boston's greatest market. I was disappointed in one thing at the outset—I could not have any breakfast before 6 o'clock, and 6 o'clock in Boston is about 7 o'clock in Ohio; therefore I walked over miles of the city, before breakfast was ready. Now for the vegetables seen displayed in such wonderful profusion, right close by this large hotel. Well, for breakfast I had just *two baked potatoes*—not another thing in the vegetable line.

At one of the railroad eating-houses on the way home I was served with a dinner comprising almost all vegetables grown in gardening. It cost 75 cents. I took breakfast on the dining-cars, for which I paid one dollar. I hope you will excuse me for saying that it seems almost wicked to pay a dollar for a breakfast, especially where one's wants are few and simple. One reason why I decided to have a dollar breakfast was, that I wanted to see if I should find the products of the garden as well as of the apiary here. I was abundantly satisfied. The dining-car proprietors not only provided almost every vegetable in their bill of fare, known to the garden, but the dishes were cooked with wonderful culinary skill. The waiters were pleasant and courteous, and the whole paraphernalia of the dining-table is like a beautiful picture. Fruits are served from almost every clime, and these, too, are the best and *handsomest* that can be bought for money. I confess that I greatly enjoyed such a breakfast, for the proprietors evidently spared no pains to make it worth a whole dollar; and the thought that you were sweeping over the landscape at the rate of forty miles an hour while you sipped most excellent coffee, and tasted of the viands prepared with the best skill that the present age affords, helped to make one feel that a dollar invested occasionally in this way was not so very bad an investment after all. The market-gardener who supplies the dining-room cars ought to be one of the most progressive ones of the present age.

Now, then, is it advisable to let vegetables and garden-stuffs have a place on our tables every day? and should they enter largely into what goes to make up our "daily bread"? I think that, in a sanitary point of view, the question has been fully decided. It is true, people sometimes get into summer difficulties by eating fresh fruits and vegetables; but I believe such troubles are brought about oftener by a scarcity of fruits and vegetables than by a surfeit; that is, on tables where fruits and vegetables are seldom seen, everybody is so ravenous for them when they make their appearance, nature is upset by too large a dose on too short notice; whereas, had there been fruits and vegetables at each meal, more or less, *the year round*, nature would suffer no such shock, and no bad results would follow.

The appointments of the meal I mentioned, in the dining-room car, were such as to make one feel pleasant and happy; now, of course, I would not recommend that every day laborer or farmer should deck his breakfast-table with cut glass and silver; but I do think there might be a very great improvement, and with no great outlay either. The women-folks (if not overworked) are ready and willing, and will gladly do their part. A few flowers put in some pretty little vase might prove one of the best investments ever made for the breakfast-table, just because the sight of them calls out our better feelings. Now, a surprise in the way of new vegetables nicely prepared may accomplish the same object; and suppose they should divert conversation during the meal to the discussion of new fruits and vegetables, seed catalogues, etc.; suppose, when the radishes are passed, Johnnie proudly announces that *he* raised them in *his* garden; or suppose that papa announces that the peas we have for dinner are the celebrated Stratagems, advertised through the papers so much, and through the seed catalogues, and so on; who can estimate the effect on these little characters just forming, gathered around the family board, in contrast with having the talk during the meal occupied by scandal or neighborhood quarrels, lawsuits, and such like? I need not tell you how hard the mother toils to provide food that she knows the little ones like. Who has not noticed her smile of pleasure when some little chick announces, "O mother! where did you get such nice squash? I like squash, *I* do."

Now, my friends, we can not all of us be engaged in agriculture as farmers, but we can be gardeners, at least to the extent I have described on some of the earlier pages of this book; and whatever our calling or profession, we must certainly meet together to take some food of some kind, at least two or three times a day—three times, I believe, as a rule. What can we do to make these meetings profitable, and to strive to have them lead toward righteousness and godliness? I feel sure that one great means of leading our little flocks heavenward is by the associations of these daily meals; and when the head of the family bows his head to give thanks to the all-wise and kind Creator, is it not his duty to see that the table is well supplied with something to make the simple prayer consistent? Let there be something placed before the little ones to lead them to feel thankful to the great Giver of all good. What shall it be but the products of the soil, largely, even if such products must come from the market-wagon?

Fruits and vegetables are already largely used for presents to the sick, presents to friends, and for presents to the loved ones at home. Some years ago I happened to be in the large city of Cleveland, in company with my old pastor, Rev. A. T. Reed. A little before train time he made the remark that he never liked to go home from the city without taking some sort of a little present for the children. What should it be? and who has not had similar feelings? Great shops and stores were all about us, holding out inducements to purchasers, and many of these shops and stores were kept to supply this very want. What sort of a present should a minister of the gospel carry to his children? I watched him with much interest. He went to a green-grocer's, and purchased a little basket—one that held about a peck, for instance. The basket cost only a nickel, but it was new and clean. This made it proper for the occasion and circumstances. Now, then, for the contents. I believe it was mostly if not all vegetables from the garden. As it was early in the spring, no such things had at that time appeared in our Medina market, and I especially remarked how handsome a bunch of beets looked. They were grown rapidly under glass, and were some of the choice varieties advertised in our seed catalogues, that look so very tempting when first taken from the soil. The tops looked fresh and green also. Well, the sight of the contents of that basket had something to do with giving me the "garden fever." The basket and contents cost some 30 or 40 cents; but as I glanced at them repeatedly I could not help but think I agreed with him that there was nothing in that whole great city so pleasing and appropriate for the loved ones at home as this little simple token of his love and remembrance of them—a little basket of garden vegetables. I have always had a particular fancy for beets and radishes tied up in neat little bunches ever since that time; and while I think of it, early beets are one of the things with which the market has never been overstocked, to my knowledge. For many months during this season just passed, early beets retailed in Cleveland at 10 cts. per bunch, or 80 or 90 cts. per dozen bunches. At the same time, fine large bunches of radishes and onions were selling for 15 to 20 cts. per dozen bunches. Some way it seemed as if the great vegetable-loving public could never get beets enough.

Early beets were the second crop on our "New Agriculture" grounds; that is, they were planted between the lettuce; and when the lettuce was all sold off, the beets came on. The boys on the wagon reported every day, right along, "Beets sold out, and more wanted." And so the demand kept up until I began to be greatly astonished. After people began to have plenty of them in their gardens, however, the demand dropped off. They are hardy, and easy to raise. Thousands of plants can be easily secured in boxes in the greenhouse, or in boxes in the windows I have described; and just as soon as the weather will permit any thing to grow at all outdoors, with the right kind of soil and a protected situation the beets will take right hold and thrive. I think it would be an excellent investment to build cheap hotbeds or greenhouses expressly for early beets and nothing else. I think a good demand for them would spring up in almost any locality.

To be continued Oct. 15.

HEADS OF GRAIN
FROM DIFFERENT FIELDS.

THAT NEWLY DISCOVERED, NAMELESS BEE-DISEASE.

DON'T call it a new disease, for it may prove to be an old one. I first noticed it some three or four years ago in the summer time, among some bees I had recently purchased. I had lost most of my bees one cold winter, and bought 12 two-frame nucleus colonies, and used my old combs. I paid but little attention to it at first, thinking it was something temporary, and perhaps similar to what I had often noticed among bees late in autumn. It did not disappear; but the next spring and summer, and even since, that same kind of used-up fellows are to be found in front of a few hives. Perhaps the old combs had something to do with it. I have thought the trouble might be caused by some vegetable or animal parasite. Something has made the fur fly on them. I suppose a parasite might do this, or could not the bee get rid of the fur itself while scratching around to get relieved of the difficulty? The other bees also might have something to do about it, as they often drive them out as they do drones, only I never saw them trying to sting one. It does not spread very fast. I think it is slightly contagious, but not at all infectious. None of my swarms have been ruined by it, but it must be injurious to have a few dropping prematurely out of the ranks every day. I prefer to see them all wearing themselves out by gathering honey all *the day* long from "every opening flower."

Walpole, N. H., Aug. 23, 1886. J. L. HUBBARD.

I should judge from your description that you have something very near akin to the nameless bee-disease. We have generally cured that phase of the nameless disease which has visited our apiary by the introduction of a new queen. It would seem, however, that yours originated with the combs or brood.

RETURNING SWARMS.

On p. 623, GLEANINGS for Aug. 1, Mr. J. E. Pond, Jr., comments upon my article in regard to returning swarms. He does not seem to understand whether my plan is to be used only in "accidental cases" or otherwise. I would suggest, that my plan be used only when swarms issue, no matter whether swarming be the *general rule* or the exception. Of course, my plan would not work *very well* if *no swarms issued;* and if swarming be *entirely prevented,* there would be no swarms to return. Now, I do not claim that returning swarms will give the largest yield of honey, or that the bees will do better otherwise by being returned. It is simply a plan to return swarms to the parent stock. I think, though, they will do as well returned as when drone and queen traps are used to prevent swarming. Mr. Pond has not read the article correctly. He speaks about the trouble of watching to see which hive the bees issued from. The beauty of my plan is, that it is *not* necessary to know which hive the swarm came from. The queens being removed, the bees will return to their own hive, even if swarms unite, as they generally will when they issue at the same time, and you do not have to watch your apiary any more than usual. I have returned swarms all summer, and no not know of an instance where they went into any other hive than their own.

DRONE-EXCLUDERS.

Queen and drone traps can not always be used. Young queens and drones must fly out. They can not be confined to the hives. It will not do to depend too much on drone-traps, and I will suggest how they might fail to prevent swarming. They will keep in the queen, but not the bees. We will suppose the swarming fever has broken out in a colony, and that a swarm from a neighboring apiary should come by. The bees would probably unite with this swarm, leaving their queen in the trap. CHAS. A. WOOD.

Tarrytown, N. Y., Sept., 1886.

We agree with you in regard to the queen-trap. It is not calculated to *prevent* swarming, strictly speaking, though it may discourage it, but to automatically *catch* the queen when the swarm does issue. This accomplishes the same result as clipping the queen's wing; but with the trap the apiarist is saved the trouble of catching the queen. Moreover, all her fair proportions are preserved.—It is true, if the trap is allowed to remain attached to the hive, the bees, after making several attempts to swarm, taking with them the queen, will by and by become disgusted with her majesty. The probable outcome will then result in her death. In the A B C of Bee Culture, now under revision, I caution beginners in regard to this very particular.

KEEPING HONEY.
